# Ginkgo

Generated from pipelines/99325737 branch based on master. Ginkgo version 1.1.1

Generated by Doxygen 1.8.16

1 Main Page	1
1.0.0.1 Modules	1
2 Installation Instructions	3
2.0.1 Building	3
2.0.2 Third party libraries and packages	5
2.0.3 Installing Ginkgo	5
3 Testing Instructions	7
3.0.1 Running the unit tests	7
3.0.1.1 Using make test	7
3.0.1.2 Using CTest	7
4 Running the benchmarks	9
5 Example programs	11
6 The custom-logger program	15
7 The custom-matrix-format program	23
8 The custom-stopping-criterion program	31
9 The external-lib-interfacing program	37
10 The ginkgo-overhead program	59
11 The ginkgo-ranges program	63
12 The ilu-preconditioned-solver program	67
13 The inverse-iteration program	71
14 The minimal-cuda-solver program	77
15 The nine-pt-stencil-solver program	79
16 The papi-logging program	87
17 The performance-debugging program	93
18 The poisson-solver program	105
19 The preconditioned-solver program	111
20 The simple-solver program	115
21 The simple-solver-logging program	119
22 The three-pt-stencil-solver program	127

23 The twentyseven-pt-stencil-solver program	135

# Main Page

This is the main page for the Ginkgo library pdf documentation. The repository is hosted on github. Documentation on aspects such as the build system, can be found at the Installation Instructions page. The Example programs can help you get started with using Ginkgo.

#### 1.0.0.1 Modules

The Ginkgo library can be grouped into modules and these modules form the basic building blocks of Ginkgo. The modules can be summarized as follows:

- Executors: Where do you want your code to be executed?
- · Linear Operators: What kind of operation do you want Ginkgo to perform?
  - Solvers : Solve a linear system for a given matrix.
  - Preconditioners: Precondition a system for a solve.
  - SpMV employing different Matrix formats: Perform a sparse matrix vector multiplication with a particular matrix format.
- Logging : Monitor your code execution.
- Stopping criteria: Manage your iteration stopping criteria.

2 Main Page

## **Installation Instructions**

#### 2.0.1 Building

#### Use the standard cmake build procedure:

```
mkdir build; cd build
cmake -G "Unix Makefiles" [OPTIONS] .. && make
```

Use cmake --build . in some systems like MinGW or Microsoft Visual Studio which do not use make.

For Microsoft Visual Studio, use cmake --build . --config <build\_type> to decide the build type. The possible options are Debug, Release, RelWithDebInfo and MinSizeRel.

Replace <code>[OPTIONS]</code> with desired cmake options for your build. Ginkgo adds the following additional switches to control what is being built:

- -DGINKGO\_DEVEL\_TOOLS={ON, OFF} sets up the build system for development (requires clangformat, will also download git-cmake-format), default is ON.
- -DGINKGO\_BUILD\_TESTS={ON, OFF} builds Ginkgo's tests (will download googletest), default is ON.
- -DGINKGO\_BUILD\_BENCHMARKS={ON, OFF} builds Ginkgo's benchmarks (will download gflags and rapidjson), default is ON.
- -DGINKGO\_BUILD\_EXAMPLES={ON, OFF} builds Ginkgo's examples, default is ON
- -DGINKGO\_BUILD\_EXTLIB\_EXAMPLE={ON, OFF} builds the interfacing example with deal.II, default is OFF.
- -DGINKGO\_BUILD\_REFERENCE={ON, OFF} build reference implementations of the kernels, useful for testing, default is ON
- -DGINKGO\_BUILD\_OMP={ON, OFF} builds optimized OpenMP versions of the kernels, default is OFF
- -DGINKGO\_BUILD\_CUDA={ON, OFF} builds optimized cuda versions of the kernels (requires CUDA), default is OFF
- -DGINKGO\_BUILD\_DOC={ON, OFF} creates an HTML version of Ginkgo's documentation from inline comments in the code. The default is OFF.
- -DGINKGO\_DOC\_GENERATE\_EXAMPLES={ON, OFF} generates the documentation of examples in Ginkgo. The default is ON.
- -DGINKGO\_DOC\_GENERATE\_PDF={ON, OFF} generates a PDF version of Ginkgo's documentation from inline comments in the code. The default is OFF.

4 Installation Instructions

• -DGINKGO\_DOC\_GENERATE\_DEV={ON, OFF} generates the developer version of Ginkgo's documentation. The default is OFF.

- -DGINKGO\_EXPORT\_BUILD\_DIR={ON, OFF} adds the Ginkgo build directory to the CMake package registry. The default is OFF.
- -DGINKGO\_WITH\_CLANG\_TIDY={ON, OFF} makes Ginkgo call clang-tidy to find programming issues. The path can be manually controlled with the CMake variable -DGINKGO\_CLANG\_TIDY\_PA 
  TH=<path>. The default is OFF.
- -DGINKGO\_WITH\_IWYU={ON, OFF} makes Ginkgo call iwyu to find include issues. The path can be manually controlled with the CMake variable -DGINKGO\_IWYU\_PATH=<path>. The default is OFF.
- -DGINKGO\_VERBOSE\_LEVEL=integer sets the verbosity of Ginkgo.
  - 0 disables all output in the main libraries,
  - 1 enables a few important messages related to unexpected behavior (default).
- -DCMAKE\_INSTALL\_PREFIX=path sets the installation path for make install. The default value is usually something like /usr/local.
- -DCMAKE\_BUILD\_TYPE=type specifies which configuration will be used for this build of Ginkgo. The default is RELEASE. Supported values are CMake's standard build types such as DEBUG and RELEASE and the Ginkgo specific COVERAGE, ASAN (AddressSanitizer) and TSAN (ThreadSanitizer) types.
- -DBUILD\_SHARED\_LIBS={ON, OFF} builds ginkgo as shared libraries (OFF) or as dynamic libraries (ON), default is ON.
- -DGINKGO\_JACOBI\_FULL\_OPTIMIZATIONS={ON, OFF} use all the optimizations for the CUDA Jacobi algorithm. OFF by default. Setting this option to ON may lead to very slow compile time (>20 minutes) for the jacobi\_generate\_kernels.cu file and high memory usage.
- -DCMAKE\_CUDA\_HOST\_COMPILER=path instructs the build system to explicitly set CUDA's host compiler to the path given as argument. By default, CUDA uses its toolchain's host compiler. Setting this option may help if you're experiencing linking errors due to ABI incompatibilities. This option is supported since CMake 3.8 but documented starting from 3.10.
- -DGINKGO\_CUDA\_ARCHITECTURES=<list> where <list> is a semicolon (;) separated list of architectures. Supported values are:
  - Auto
  - Kepler, Maxwell, Pascal, Volta
  - CODE, CODE (COMPUTE), (COMPUTE)

Auto will automatically detect the present CUDA-enabled GPU architectures in the system. Kepler, Maxwell, Pascal and Volta will add flags for all architectures of that particular NVIDIA GPU generation. COMPUTE and CODE are placeholders that should be replaced with compute and code numbers (e.g. for compute\_70 and sm\_70 COMPUTE and CODE should be replaced with 70. Default is Auto. For a more detailed explanation of this option see the ARCHITECTURES specification list section in the documentation of the CudaArchitectureSelector CMake module.

- -DGINKGO\_WINDOWS\_SHARED\_LIBRARY\_RELPATH=<path> where <path> is a relative path built with PROJECT\_BINARY\_DIR. Users must add the absolute path (PROJECT\_BINARY\_DIR/GINKG← O\_WINDOWS\_SHARED\_LIBRARY\_RELPATH) into the environment variable PATH when building shared libraries and executable program, default is windows\_shared\_library.
- -DGINKGO\_CHECK\_PATH={ON, OFF} checks if the environment variable PATH is valid. It is checked only when building shared libraries and executable program, default is ON.

For example, to build everything (in debug mode), use:

```
cmake -G "Unix Makefiles" -H. -BDebug -DCMAKE_BUILD_TYPE=Debug -DGINKGO_DEVEL_TOOLS=ON \
-DGINKGO_BUILD_TESTS=ON -DGINKGO_BUILD_REFERENCE=ON -DGINKGO_BUILD_OMP=ON \
-DGINKGO_BUILD_CUDA=ON \
cmake --build Debug
```

NOTE: Ginkgo is known to work with the Unix Makefiles and Ninja based generators. Other CMake generators are untested.

#### 2.0.2 Third party libraries and packages

Ginkgo relies on third party packages in different cases. These third party packages can be turned off by disabling the relevant options.

- GINKGO\_BUILD\_CUDA=ON: CudaArchitectureSelector (CAS) is a CMake helper to manage CUDA architecture settings;
- GINKGO BUILD TESTS=ON: Our tests are implemented with Google Test;
- GINKGO\_BUILD\_BENCHMARKS=ON: For argument management we use gflags and for JSON parsing we use RapidJSON;
- GINKGO\_DEVEL\_TOOLS=ON: git-cmake-format is our CMake helper for code formatting.

By default, Ginkgo uses the internal version of each package. For each of the packages GTEST, GFLAGS, Reapid and CAS, it is possible to force Ginkgo to try to use an external version of a package. For this, Ginkgo provides two ways to find packages. To rely on the CMake find\_package command, use the CMake option -DGINKGO\_USE\_EXTERNAL\_<package>=ON. Note that, if the external packages were not installed to the default location, the CMake option -DCMAKE\_PREFIX\_PATH=<path-list> needs to be set to the semicolon (;) separated list of install paths of these external packages. For more Information, see the CMake documentation for CMAKE\_PREFIX\_PATH for details.

To manually configure the paths, Ginkgo relies on the standard xSDK Installation policies for all packages except CAS (as it is neither a library nor a header, it cannot be expressed through the TPL format):

- -DTPL\_ENABLE\_<package>=ON
- -DTPL\_<package>\_LIBRARIES=/path/to/libraries.{so|a}
- -DTPL\_<package>\_INCLUDE\_DIRS=/path/to/header/directory

When applicable (e.g. for GTest libraries), a ; separated list can be given to the  $\mathtt{TPL} < \mathtt{package} > \_\{\mathtt{LIBR} \leftarrow \mathtt{ARIES} | \mathtt{INCLUDE} \ \mathtt{DIRS} \}$  variables.

#### 2.0.3 Installing Ginkgo

To install Ginkgo into the specified folder, execute the following command in the build folder make install

If the installation prefix (see  $\texttt{CMAKE\_INSTALL\_PREFIX}$ ) is not writable for your user, e.g. when installing Ginkgo system-wide, it might be necessary to prefix the call with sudo.

After the installation, CMake can find ginkgo with  $find\_package$  (Ginkgo). An example can be found in the test\\_install.

6 Installation Instructions

# **Testing Instructions**

#### 3.0.1 Running the unit tests

You need to compile ginkgo with <code>-DGINKGO\_BUILD\_TESTS=ON</code> option to be able to run the tests.

#### 3.0.1.1 Using make test

After configuring Ginkgo, use the following command inside the build folder to run all tests:

The output should contain several lines of the form:

To run only a specific test and see more details results (e.g. if a test failed) run the following from the build folder:

where path/to/test is the path returned by make test.

#### 3.0.1.2 Using CTest

The tests can also be ran through CTest from the command line, for example when in a configured build directory: CTEST - T STATT - T S

Will start a new test campaign (usually in Experimental mode), build Ginkgo with the set configuration, run the tests and submit the results to our CDash dashboard.

Another option is to use Ginkgo's CTest script which is configured to build Ginkgo with default settings, runs the tests and submits the test to our CDash dashboard automatically.

To run the script, use the following command:

```
ctest -S cmake/CTestScript.cmake
```

The default settings are for our own CI system. Feel free to configure the script before launching it through variables or by directly changing its values. A documentation can be found in the script itself.

8 Testing Instructions

# Running the benchmarks

In addition to the unit tests designed to verify correctness, Ginkgo also includes a benchmark suite for checking its performance on the system. To compile the benchmarks, the flag <code>-DGINKGO\_BUILD\_BENCHMARKS=ON</code> has to be set during the <code>cmake</code> step. In addition, the <code>ssget command-line utility</code> has to be installed on the system.

The benchmark suite tests Ginkgo's performance using the SuiteSparse matrix collection and artificially generated matrices. The suite sparse collection will be downloaded automatically when the benchmarks are run. Please note that the entire collection requires roughly 100GB of disk storage in its compressed format, and roughly 25GB of additional disk space for intermediate data (such us uncompressing the archive). Additionally, the benchmark runs usually take a long time (SpMV benchmarks on the complete collection take roughly 24h using the K20 GPU), and will stress the system.

The benchmark suite is invoked using the make benchmark command in the build directory. The behavior of the suite can be modified using environment variables. Assuming the bash shell is used, these can either be specified via the export command to persist between multiple runs:

```
export VARIABLE="value" ....
make benchmark
```

or specified on the fly, on the same line as the make benchmark command:

env VARIABLE="value" ... make benchmark

Since make sets any variables passed to it as temporary environment variables, the following shorthand can also be used:

```
make benchmark VARIABLE="value" ...
```

A combination of the above approaches is also possible (e.g. it may be useful to export the  $SYSTEM_NAME$  variable, and specify the others at every benchmark run).

Supported environment variables are described in the following list:

- BENCHMARK={spmv, solver, preconditioner} The benchmark set to run. Default is spmv.
  - spmv Runs the sparse matrix-vector product benchmarks on the SuiteSparse collection.
  - solver Runs the solver benchmarks on the SuiteSparse collection. The matrix format is determined by running the spmv benchmarks first, and using the fastest format determined by that benchmark.
     The maximum number of iterations for the iterative solvers is set to 10,000 and the requested residual reduction factor to 1e-6.
  - preconditioner Runs the preconditioner benchmarks on artificially generated block-diagonal matrices.

- DRY\_RUN={true, false} If set to true, prepares the system for the benchmark runs (downloads the collections, creates the result structure, etc.) and outputs the list of commands that would normally be run, but does not run the benchmarks themselves. Default is false.
- EXECUTOR={reference, cuda, omp} The executor used for running the benchmarks. Default is cuda.
- SEGMENTS=<N> Splits the benchmark suite into <N> segments. This option is useful for running the benchmarks on an HPC system with a batch scheduler, as it enables partitioning of the benchmark suite and running it concurrently on multiple nodes of the system. If specified, SEGMENT\_ID also has to be set. Default is 1.
- SEGMENT\_ID=<I> used in combination with the SEGMENTS variable. <I> should be an integer between 1 and <N>. If specified, only the <I>-th segment of the benchmark suite will be run. Default is 1.
- SYSTEM\_NAME=<name> the name of the system where the benchmarks are being run. This option only changes the directory where the benchmark results are stored. It can be used to avoid overwriting the benchmarks if multiple systems share the same filesystem, or when copying the results between systems. Default is unknown.

Once make benchmark completes, the results can be found in <Ginkgo build directory>/benchmark/results/<
YSTEM\_NAME>/. The files are written in the JSON format, and can be analyzed using any of the data analysis
tools that support JSON. Alternatively, they can be uploaded to an online repository, and analyzed using Ginkgo's
free web tool <a href="Ginkgo Performance Explorer">Ginkgo Performance Explorer</a> (GPE). (Make sure to change the "Performance data
URL" to your repository if using GPE.)

# **Example programs**

Here you can find example programs that demonstrate the usage of Ginkgo. Some examples are built on one another and some are stand-alone and demonstrate a concept of Ginkgo, which can be used in your own code.

You can browse the available example programs

- 1. as a graph that shows how example programs build upon each other.
- 2. as a list that provides a short synopsis of each program.
- 3. or grouped by topic.

By default, all Ginkgo examples are built using CMake.

An example for building the examples and using Ginkgo as an external library without CMake can be found in the script provided for each example, which should be called with the form: ./build.sh PATH\_TO\_GINKGO\_B UILD\_DIR

By default, Ginkgo is compiled with at least <code>-DGINKGO\_BUILD\_REFERENCE=ON</code>. To execute on a GPU, you need to have a GPU on the system and must have compiled Ginkgo with the <code>-DGINKGO\_BUILD\_CUDA=ON</code> option.

#### Connections between example programs

The following graph shows the connections between example programs and how they build on each other. Click on any of the boxes to go to one of the programs. If you hover your mouse pointer over a box, a brief description of the program should appear.

12 Example programs

### Legend:

### **Example programs**

The simple-solver program	A minimal CG solver in Ginkgo, which reads a matrix from a file.
The minimal-cuda-solver program	A minimal solver on the CUDA executor than can be run on NVI← DIA GPU's.
The poisson-solver program	Solve an actual physically relevant problem, the poisson problem. The matrix is generated within Ginkgo.
The preconditioned-solver program	Using a Jacobi preconditioner to solve a linear system.
The ilu-preconditioned-solver program	Using an ILU preconditioner to solve a linear system.
The performance-debugging program	Using Loggers to debug the performance within Ginkgo.
The three-pt-stencil-solver program	Using a three point stencil to solve the poisson equation with array views.
The nine-pt-stencil-solver program	Using a nine point 2D stencil to solve the poisson equation with array views.
The twentyseven-pt-stencil-solver program	Using a twentyseven point 3D stencil to solve the poisson equation with array views.
The external-lib-interfacing program	Using Ginkgo's solver with the external library deal.II.
The custom-logger program	Creating a custom logger specifically for comparing the recurrent and the real residual norms.
The custom-matrix-format program	Creating a matrix-free stencil solver by using Ginkgo's advanced methods to build your own custom matrix format.
The inverse-iteration program	Using Ginkgo to compute eigenvalues of a matrix with the inverse iteration method.
The simple-solver-logging program	Using the logging functionality in Ginkgo to get solver and other information to diagnose and debug your code.
The papi-logging program	Using the PAPI logging library in Ginkgo to get advanced information about your code and its behaviour.
The ginkgo-overhead program	Measuring the overhead of the Ginkgo library.

The custom-stopping-criterion program	Creating a custom stopping criterion for the iterative solution process.
The ginkgo-ranges program	Using the ranges concept to factorize a matrix with the LU factorization.

### **Example programs grouped by topics**

# **Chapter 6**

# The custom-logger program

The simple solver with a custom logger example..

This example depends on simple-solver, simple-solver-logging, minimal-cuda-solver.

## Introduction

The custom-logger example shows how Ginkgo's API can be leveraged to implement application-specific callbacks for Ginkgo's events. This is the most basic way of extending Ginkgo and a good first step for any application developer who wants to adapt Ginkgo to his specific needs.

Ginkgo's gko::log::Logger abstraction provides hooks to the events that happen during the library execution. These hooks concern any low-level event such as memory allocations, deallocations, copies and kernel launches up to high-level events such as linear operator applications and completion of solver iterations.

In this example, a simple logger is implemented to track the solver's recurrent residual norm and compute the true residual norm. At the end of the solver execution, a comparison table is shown on-screen.

## About the example

Each example has the following sections:

- 1. **Introduction:**This gives an overview of the example and mentions any interesting aspects in the example that might help the reader.
- 2. **The commented program:** This section is intended for you to understand the details of the example so that you can play with it and understand Ginkgo and its features better.
- 3. **Results:** This section shows the results of the code when run. Though the results may not be completely the same, you can expect the behaviour to be similar.
- 4. **The plain program:** This is the complete code without any comments to have an complete overview of the code.

## The commented program

#### Include files

This is the main ginkgo header file.

```
#include <ginkgo/ginkgo.hpp>
```

Add the fstream header to read from data from files.

```
#include <fstream>
```

Add the C++ iomanip header to prettify the output.

```
#include <iomanip>
```

Add formatting flag modification capabilities.

```
#include <ios>
```

Add the C++ iostream header to output information to the console.

```
#include <iostream>
```

Add the string manipulation header to handle strings.

```
#include <string>
```

Add the vector header for storing the logger's data

```
#include <vector>
```

Utility function which gets the scalar value of a Ginkgo gko::matrix::Dense matrix representing the norm of a vector.

```
template <typename ValueType>
double get_norm(const gko::matrix::Dense<ValueType> *norm)
{
```

```
Put the value on CPU thanks to the master executor
```

```
auto cpu_norm = clone(norm->get_executor()->get_master(), norm);
```

```
Return the scalar value contained at position (0, 0)
```

```
return cpu_norm->at(0, 0);
```

Utility function which computes the norm of a Ginkgo gko::matrix::Dense vector.

```
template <typename ValueType>
double compute_norm(const gko::matrix::Dense<ValueType> *b)
```

### Get the executor of the vector

```
auto exec = b->get_executor();
```

### Initialize a result scalar containing the value 0.0.

```
auto b_norm = gko::initialize<gko::matrix::Dense<ValueType»({0.0}, exec);</pre>
```

Use the dense  ${\tt compute\_norm2}$  function to compute the norm.

```
b->compute_norm2(lend(b_norm));
```

Use the other utility function to return the norm contained in b\_norm`

```
return get_norm(lend(b_norm));
}
```

Custom logger class which intercepts the residual norm scalar and solution vector in order to print a table of real vs recurrent (internal to the solvers) residual norms.

```
template <typename ValueType>
struct ResidualLogger : gko::log::Logger {
```

## Output the logger's data in a table format

```
void write() const
```

### Print a header for the table

```
std::cout « "Recurrent vs real residual norm:" « std::endl;
std::cout « ' |' « std::setw(10) « "Iteration" « ' |' « std::setw(25)
```

```
\ll "Recurrent Residual Norm" \ll '\mid' \ll std::setw(25) \ll "Real Residual Norm" \ll '\mid' \ll std::endl;
Print a separation line. Note that for creating 10 characters std::setw() should be set to 11.
std::cout " ' ' " std::setfill('-') " std::setw(11) " " std::setw(26) " ' | ' " std::setw(26) " ' | '
          « std::setfill(' ') « std::endl;
Print the data one by one in the form
std::cout « std::scientific;
for (std::size_t i = 0; i < iterations.size(); i++) {
    std::cout « '|' « std::setw(10) « iterations[i] « '|'</pre>
             }
std::defaultfloat could be used here but some compilers do not support it properly, e.g. the Intel compiler
std::cout.unsetf(std::ios_base::floatfield);
Print a separation line
    std::cout « '|' « std::setfill('-') « std::setw(11) « '|'
              using gko_dense = gko::matrix::Dense<ValueType>;
Customize the logging hook which is called everytime an iteration is completed
void on_iteration_complete(const gko::LinOp *,
                            const gko::size_type &iteration,
                            const gko::LinOp *residual,
                            const gko::LinOp *solution,
                            const gko::LinOp *residual_norm) const override
{
If the solver shares a residual norm, log its value
if (residual_norm) {
    auto dense_norm = gko::as<gko_dense>(residual_norm);
Add the norm to the recurrent_norms vector
recurrent_norms.push_back(get_norm(dense_norm));
Otherwise, use the recurrent residual vector
    auto dense_residual = gko::as<gko_dense>(residual);
Compute the residual vector's norm
auto norm = compute_norm(gko::lend(dense_residual));
Add the computed norm to the recurrent_norms vector
    recurrent_norms.push_back(norm);
If the solver shares the current solution vector
Store the matrix's executor
auto exec = matrix->get_executor();
Create a scalar containing the value 1.0
auto one = gko::initialize<gko_dense>({1.0}, exec);
Create a scalar containing the value -1.0
auto neg_one = gko::initialize<gko_dense>({-1.0}, exec);
```

## Instantiate a temporary result variable auto res = gko::clone(b);

Compute the real residual vector by calling apply on the system matrix

```
Compute the norm of the residual vector and add it to the real norms vector
    real_norms.push_back(compute_norm(gko::lend(res)));
} else {
Add to the real_norms vector the value -1.0 if it could not be computed
    real_norms.push_back(-1.0);
Add the current iteration number to the iterations vector
    iterations.push_back(iteration);
Construct the logger and store the system matrix and b vectors
    ResidualLogger(std::shared_ptr<const gko::Executor> exec,
                   const gko::LinOp *matrix, const gko_dense *b)
        : gko::log::Logger(exec, gko::log::Logger::iteration_complete_mask),
          matrix{matrix},
          b{b}
    {}
private:
Pointer to the system matrix
const gko::LinOp *matrix;
Pointer to the right hand sides
const qko_dense *b;
Vector which stores all the recurrent residual norms
mutable std::vector<ValueType> recurrent_norms{};
Vector which stores all the real residual norms
mutable std::vector<ValueType> real_norms{};
Vector which stores all the iteration numbers
    mutable std::vector<std::size_t> iterations{};
```

Use some shortcuts. In Ginkgo, vectors are seen as a gko::matrix::Dense with one column/one row. The advantage of this concept is that using multiple vectors is a now a natural extension of adding columns/rows are necessary.

using vec = gko::matrix::Dense<>;

The gko::matrix::Csr class is used here, but any other matrix class such as gko::matrix::Coo, gko::matrix::Hybrid, gko::matrix::Ell or gko::matrix::Sellp could also be used.

using mtx = gko::matrix::Csr<>;

The gko::solver::Cg is used here, but any other solver class can also be used.

```
using cg = gko::solver::Cg<>;
```

int main(int argc, char \*argv[])

### Print the ginkgo version information.

```
std::cout « gko::version_info::get() « std::endl;
```

### Where do you want to run your solver?

The gko::Executor class is one of the cornerstones of Ginkgo. Currently, we have support for an gko::OmpExecutor, which uses OpenMP multi-threading in most of its kernels, a gko::ReferenceExecutor, a single threaded specialization of the OpenMP executor and a gko::CudaExecutor which runs the code on a NVIDIA GPU if available.

### Note

With the help of C++, you see that you only ever need to change the executor and all the other functions/routines within Ginkgo should automatically work and run on the executor with any other changes.

### Reading your data and transfer to the proper device.

Read the matrix, right hand side and the initial solution using the read function.

Note

Ginkgo uses C++ smart pointers to automatically manage memory. To this end, we use our own object ownership transfer functions that under the hood call the required smart pointer functions to manage object ownership. The gko::share, gko::give and gko::lend are the functions that you would need to use.

```
auto A = share(gko::read<mtx>(std::ifstream("data/A.mtx"), exec));
auto b = gko::read<vec>(std::ifstream("data/b.mtx"), exec);
auto x = gko::read<vec>(std::ifstream("data/x0.mtx"), exec);
```

### Creating the solver

Generate the gko::solver factory. Ginkgo uses the concept of Factories to build solvers with certain properties. Observe the Fluent interface used here. Here a cg solver is generated with a stopping criteria of maximum iterations of 20 and a residual norm reduction of 1e-15. You also observe that the stopping criteria(gko::stop) are also generated from factories using their build methods. You need to specify the executors which each of the object needs to be built on.

Add the previously created logger to the solver factory. The logger will be automatically propagated to all solvers created from this factory.

gko::lend(b));

```
solver_gen->add_logger(logger);
```

Generate the solver from the matrix. The solver factory built in the previous step takes a "matrix" (a gko::LinOp to be more general) as an input. In this case we provide it with a full matrix that we previously read, but as the solver only effectively uses the apply() method within the provided "matrix" object, you can effectively create a gko::LinOp class with your own apply implementation to accomplish more tasks. We will see an example of how this can be done in the custom-matrix-format example

```
auto solver = solver_gen->generate(A);
```

Finally, solve the system. The solver, being a gko::LinOp, can be applied to a right hand side, b to obtain the solution, x.

```
solver->apply(lend(b), lend(x));
```

Print the solution to the command line.

```
std::cout « "Solution (x): \n";
write(std::cout, lend(x));
```

Print the table of the residuals obtained from the logger

```
logger->write();
```

To measure if your solution has actually converged, you can measure the error of the solution. one, neg\_one are objects that represent the numbers which allow for a uniform interface when computing on any device. To compute the residual, all you need to do is call the apply method, which in this case is an spmv and equivalent to the LAPACK z\_spmv routine. Finally, you compute the euclidean 2-norm with the compute\_norm2 function.

```
auto one = gko::initialize<vec>({1.0}, exec);
auto neg_one = gko::initialize<vec>({-1.0}, exec);
auto res = gko::initialize<vec>({0.0}, exec);
A->apply(lend(one), lend(x), lend(neg_one), lend(b));
b->compute_norm2(lend(res));
std::cout « "Residual norm sqrt(r^T r): \n";
write(std::cout, lend(res));
```

## Results

## **Chapter 7**

# The custom-matrix-format program

The custom matrix format example..

This example depends on simple-solver, poisson-solver, three-pt-stencil-solver, .

### Introduction

This example solves a 1D Poisson equation:

$$u:[0,1]\rightarrow R$$

$$u"=f$$

$$u(0)=u0$$

$$u(1)=u1$$

using a finite difference method on an equidistant grid with  ${\tt K}$  discretization points ( ${\tt K}$  can be controlled with a command line parameter). The discretization is done via the second order Taylor polynomial:

For an equidistant grid with K "inner" discretization points x1,...,xk,and step size h=1/(K+1), the formula produces a system of linear equations

$$2u_1 - u_2 = -f_1h^2 + u0$$
  
-  $u(k-1) + 2u_k - u(k+1) = -f_kh^2, k = 2, ..., K-1$   
-  $u(K-1) + 2u_K = -f_Kh^2 + u1$ 

which is then solved using Ginkgo's implementation of the CG method preconditioned with block-Jacobi. It is also possible to specify on which executor Ginkgo will solve the system via the command line. The function 'f'is set to 'f(x) = 6x' (making the solution ' $u(x) = x^3$ '), but that can be changed in the main function.

The intention of this example is to show how a custom linear operator can be created and integrated into Ginkgo to achieve performance benefits.

### About the example

## The commented program

```
#include <iostream>
#include <map>
#include <string>
#include <omp.h>
#include <oinkgo/ginkgo.hpp>
```

A CUDA kernel implementing the stencil, which will be used if running on the CUDA executor. Unfortunately, NVCC has serious problems interpreting some parts of Ginkgo's code, so the kernel has to be compiled separately.

A stencil matrix class representing the 3pt stencil linear operator. We include the gko::EnableLinOp mixin which implements the entire LinOp interface, except the two apply\_impl methods, which get called inside the default implementation of apply (after argument verification) to perform the actual application of the linear operator. In addition, it includes the implementation of the entire PolymorphicObject interface.

It also includes the gko::EnableCreateMethod mixin which provides a default implementation of the static create method. This method will forward all its arguments to the constructor to create the object, and return an std ::unique ptr to the created object.

This constructor will be called by the create method. Here we initialize the coefficients of the stencil.

Here we implement the application of the linear operator, x = A \* b. apply\_impl will be called by the apply method, after the arguments have been moved to the correct executor and the operators checked for conforming sizes.

For simplicity, we assume that there is always only one right hand side and the stride of consecutive elements in the vectors is 1 (both of these are always true in this example).

```
void apply_impl(const gko::LinOp *b, gko::LinOp *x) const override
{
```

we only implement the operator for dense RHS. gko::as will throw an exception if its argument is not Dense.

```
auto dense_b = gko::as<vec>(b);
auto dense_x = gko::as<vec>(x);
```

we need separate implementations depending on the executor, so we create an operation which maps the call to the correct implementation

## OpenMP implementation

```
void run(std::shared_ptr<const gko::OmpExecutor>) const override
{
    auto b_values = b->get_const_values();
    auto x_values = x->get_values();

#pragma omp parallel for
    for (std::size_t i = 0; i < x->get_size()[0]; ++i) {
        auto coefs = coefficients.get_const_data();
        auto result = coefs[1] * b_values[i];
        if (i > 0) {
            result += coefs[0] * b_values[i - 1];
        }
        if (i < x->get_size()[0] - 1) {
```

```
result += coefs[2] * b_values[i + 1];
}
x_values[i] = result;
}
```

### **CUDA** implementation

We do not provide an implementation for reference executor. If not provided, Ginkgo will use the implementation for the OpenMP executor when calling it in the reference executor.

```
const coef_type &coefficients;
const vec *b;
vec *x;
};
this->get_executor()->run(
stencil_operation(coefficients, dense_b, dense_x));
```

There is also a version of the apply function which does the operation x = alpha \* A \* b + beta \* x. This function is commonly used and can often be better optimized than implementing it using x = A \* b. However, for simplicity, we will implement it exactly like that in this example.

Creates a stencil matrix in CSR format for the given number of discretization points.

### Generates the RHS vector given f and the boundary conditions.

```
template <typename Closure>
void generate_rhs(Closure f, double u0, double u1, gko::matrix::Dense<> *rhs)
{
   const auto discretization_points = rhs->get_size()[0];
   auto values = rhs->get_values();
   const auto h = 1.0 / (discretization_points + 1);
   for (int i = 0; i < discretization_points; ++i) {
      const auto xi = (i + 1) * h;
      values[i] = -f(xi) * h * h;
   }
   values[0] += u0;
   values[discretization_points - 1] += u1;
}</pre>
```

## Prints the solution $\boldsymbol{u}$ .

```
void print_solution(double u0, double u1, const gko::matrix::Dense<> *u)
{
```

}

```
std::cout « u0 « '\n';
     for (int i = 0; i < u->get_size()[0]; ++i) {
    std::cout « u->get_const_values()[i] « '\n';
     std::cout « u1 « std::endl;
}
Computes the 1-norm of the error given the computed u and the correct solution function correct_u.
template <typename Closure>
double calculate_error(int discretization_points, const gko::matrix::Dense<> *u,
                           Closure correct_u)
     const auto h = 1.0 / (discretization_points + 1);
     auto error = 0.0;
     for (int i = 0; i < discretization_points; ++i) {</pre>
         using std::abs;
         const auto xi = (i + 1) * h;
         error +=
             abs(u->get_const_values()[i] - correct_u(xi)) / abs(correct_u(xi));
     return error;
int main(int argc, char *argv[])
Some shortcuts
using vec = gko::matrix::Dense<double>;
using mtx = gko::matrix::Csr<double, int>;
using cg = gko::solver::Cg<double>;
if (argc < 2) {
     std::cerr « "Usage: " « argv[0] « " DISCRETIZATION_POINTS [executor]"
                « std::endl;
     std::exit(-1);
}
Get number of discretization points
const unsigned int discretization_points =
   argc >= 2 ? std::atoi(argv[1]) : 100u;
const auto executor_string = argc >= 3 ? argv[2] : "reference";
Figure out where to run the code
const auto omp = gko::OmpExecutor::create();
std::map<std::string, std::shared_ptr<gko::Executor» exec_map{
     {"omp", omp),
{"cuda", gko::CudaExecutor::create(0, omp)},
     {"reference", gko::ReferenceExecutor::create()}};
executor where Ginkgo will perform the computation
const auto exec = exec_map.at(executor_string); // throws if not valid
executor used by the application
const auto app_exec = exec_map["omp"];
problem:
auto correct_u = [](double x) { return x * x * x; };
auto f = [](double x) { return 6 * x; };
auto u0 = correct_u(0);
auto u1 = correct_u(1);
initialize vectors
auto rhs = vec::create(app_exec, gko::dim<2>(discretization_points, 1));
generate_rhs(f, u0, u1, lend(rhs));
auto u = vec::create(app_exec, gko::dim<2>(discretization_points, 1));
for (int i = 0; i < u->get_size()[0]; ++i) {
    u->get_values()[i] = 0.0;
}
Generate solver and solve the system
cg::build()
     .with_criteria(gko::stop::Iteration::build()
                           .with_max_iters(discretization_points)
                           .on(exec),
                      gko::stop::ResidualNormReduction<>::build()
                           .with_reduction_factor(1e-6)
                           .on(exec))
     .on(exec)
notice how our custom StencilMatrix can be used in the same way as any built-in type
         ->generate(
              StencilMatrix::create(exec, discretization_points, -1, 2, -1))
     ->apply(lend(rhs), lend(u));
print_solution(u0, u1, lend(u));
     std::cout « "The average relative error is "
                « calculate_error(discretization_points, lend(u), correct_u) /
                        discretization_points
                « std::endl;
```

### Results

### Comments about programming and debugging

## **Chapter 8**

# The custom-stopping-criterion program

The custom stopping criterion creation example..

This example depends on simple-solver, minimal-cuda-solver.

## Introduction

### About the example

## The commented program

```
#include <ginkgo/ginkgo.hpp>
#include <fstream>
#include <iostream>
#include <string>
#include <thread>
* The ByInteraction class is a criterion which asks for user input to stop * the iteration process. Using this criterion is slightly more complex than the * other ones, because it is asynchronous therefore requires the use of threads.
class ByInteraction
    : public gko::EnablePolymorphicObject<ByInteraction, gko::stop::Criterion> {
    friend class gko::EnablePolymorphicObject<ByInteraction,</pre>
                                                      gko::stop::Criterion>;
    using Criterion = gko::stop::Criterion;
    GKO_CREATE_FACTORY_PARAMETERS(parameters, Factory)
         * Boolean set by the user to stop the iteration process
         std::add_pointer<volatile bool>::type GKO_FACTORY_PARAMETER(
             stop_iteration_process, nullptr);
    GKO_ENABLE_CRITERION_FACTORY(ByInteraction, parameters, Factory);
GKO_ENABLE_BUILD_METHOD(Factory);
protected:
    bool check_impl(gko::uint8 stoppingId, bool setFinalized,
                       gko::Array<gko::stopping_status> *stop_status,
                       bool *one_changed, const Criterion::Updater &) override
         bool result = *(parameters_.stop_iteration_process);
         if (result) {
              this->set_all_statuses(stoppingId, setFinalized, stop_status);
              *one_changed = true;
         return result;
    explicit ByInteraction(std::shared ptr<const gko::Executor> exec)
         : EnablePolymorphicObject<ByInteraction, Criterion>(std::move(exec))
```

```
explicit ByInteraction(const Factory *factory,
                              const gko::stop::CriterionArgs &args)
         : EnablePolymorphicObject<ByInteraction, Criterion>(
               factory->get_executor()),
           parameters_{factory->get_parameters()}
    { }
void run_solver(volatile bool *stop_iteration_process,
                 std::shared_ptr<gko::Executor> exec)
Some shortcuts
using mtx = gko::matrix::Csr<>;
using vec = gko::matrix::Dense<>;
using bicg = gko::solver::Bicgstab<>;
Read Data
auto A = share(gko::read<mtx>(std::ifstream("data/A.mtx"), exec));
auto b = gko::read<vec>(std::ifstream("data/b.mtx"), exec);
auto x = gko::read<vec>(std::ifstream("data/x0.mtx"), exec);
Create solver factory and solve system
auto solver = bicg::build()
                    .with_criteria(ByInteraction::build()
                                         .with_stop_iteration_process(
    stop_iteration_process)
                                          .on(exec))
                    ->generate(A);
solver->add_logger(gko::log::Stream<>::create(
   exec, gko::log::Logger::iteration_complete_mask, std::cout, true));
solver->apply(lend(b), lend(x));
std::cout « "Solver stopped" « std::endl;
Print solution
std::cout « "Solution (x): \n";
write(std::cout, lend(x));
Calculate residual
    auto one = gko::initialize<vec>((1.0), exec);
auto neg_one = gko::initialize<vec>((-1.0), exec);
    auto res = gko::initialize<vec>({0.0}, exec);
    A->apply(lend(one), lend(x), lend(neg_one), lend(b));
    b->compute_norm2(lend(res));
    std::cout « "Residual norm sqrt(r^T r): \n";
    write(std::cout, lend(res));
int main(int argc, char *argv[])
Print version information
std::cout « gko::version_info::get() « std::endl;
Figure out where to run the code
std::shared_ptr<gko::Executor> exec;
if (argc == 1 || std::string(argv[1]) == "reference") {
    exec = gko::ReferenceExecutor::create();
} else if (argc == 2 && std::string(argv[1]) == "omp") {
    exec = gko::OmpExecutor::create();
} else if (argc == 2 && std::string(argv[1]) == "cuda" &&
            gko::CudaExecutor::get_num_devices() > 0) {
    exec = gko::CudaExecutor::create(0, gko::OmpExecutor::create());
} else {
    std::cerr « "Usage: " « argv[0] « " [executor]" « std::endl;
    std::exit(-1);
Declare a user controled boolean for the iteration process
volatile bool stop_iteration_process{};
Create a new a thread to launch the solver
std::thread t(run_solver, &stop_iteration_process, exec);
```

# Look for an input command "stop" in the console, which sets the boolean to true std::cout « "Type 'stop' to stop the iteration process" « std::endl;

```
std::cout « Type Stop to Stop the Iteration process « std::end;
std::string command;
while (std::cin » command) {
   if (command == "stop") {
```

```
break;
} else {
    std::cout « "Unknown command" « std::endl;
}

std::cout « "User input command 'stop' - The solver will stop!"
    « std::endl;
stop_iteration_process = true;
t.join();
```

## Results

```
This is the expected output:
```

```
[LOG] \gg \text{ iteration 15331 completed with solver LinOp[gko::solver::Bicgstab < double > , 0x7f2f38003c10] with the other line of the solver of the solver contains t

        : EnablePolymorphicObject<ByInteraction, Criterion>(
              factory->get_executor()),
          parameters_{factory->get_parameters()}
    {}
void run_solver(volatile bool *stop_iteration_process,
                std::shared_ptr<gko::Executor> exec)
    using mtx = gko::matrix::Csr<>;
    using vec = gko::matrix::Dense<>;
    using bicg = gko::solver::Bicgstab<>;
    auto A = share(gko::read<mtx>(std::ifstream("data/A.mtx"), exec));
    auto b = gko::read<vec>(std::ifstream("data/b.mtx"), exec);
    auto x = gko::read<vec>(std::ifstream("data/x0.mtx"), exec);
    auto solver = bicg::build()
                       .with_criteria(ByInteraction::build()
                                           .with_stop_iteration_process(
                                               stop_iteration_process)
                       .on(exec)
                       ->generate(A);
    solver->add_logger(gko::log::Stream<>::create(
       exec, gko::log::Logger::iteration_complete_mask, std::cout, true));
    solver->apply(lend(b), lend(x));
std::cout « "Solver stopped" « std::endl;
    std::cout « "Solution (x): \n";
    write(std::cout, lend(x));
auto one = gko::initialize<vec>({1.0}, exec);
    auto neg_one = gko::initialize<vec>({-1.0}, exec);
    auto res = gko::initialize<vec>({0.0}, exec);
    A->apply(lend(one), lend(x), lend(neg_one), lend(b));
    b->compute_norm2(lend(res));
    std::cout « "Residual norm sqrt(r^T r): n";
    write(std::cout, lend(res));
int main(int argc, char *argv[])
    std::cout « gko::version_info::get() « std::endl;
    std::shared_ptr<gko::Executor> exec;
    if (argc == 1 \mid \mid std::string(argv[1]) == "reference") {
        exec = gko::ReferenceExecutor::create();
    } else if (argc == 2 && std::string(argv[1]) == "omp") {
        exec = gko::OmpExecutor::create();
    } else if (argc == 2 && std::string(argv[1]) == "cuda" &&
               gko::CudaExecutor::get_num_devices() > 0) {
        exec = gko::CudaExecutor::create(0, gko::OmpExecutor::create());
    } else {
       std::cerr « "Usage: " « argv[0] « " [executor]" « std::endl;
        std::exit(-1);
    volatile bool stop_iteration_process{};
    std::thread t(run_solver, &stop_iteration_process, exec);
std::cout « "Type 'stop' to stop the iteration process" « std::endl;
    std::string command;
    while (std::cin » command) {
        if (command == "stop") {
            break;
        } else {
            std::cout « "Unknown command" « std::endl;
    std::cout « "User input command 'stop' - The solver will stop!"
              « std::endl;
    stop_iteration_process = true;
    t.join();
```

# **Chapter 9**

# The external-lib-interfacing program

The external library(deal.II) interfacing example..

### Introduction

About the example

## The commented program

```
#include <deal.II/base/function.h>
#include <deal.II/base/logstream.h>
#include <deal.II/base/quadrature_lib.h>
#include <deal.II/dofs/dof_accessor.h>
#include <deal.II/dofs/dof_handler.h>
#include <deal.II/dofs/dof_tools.h>
#include <deal.II/fe/fe_q.h>
#include <deal.II/fe/fe_values.h>
#include <deal.II/grid/grid_generator.h>
#include <deal.II/grid/grid_out.h>
#include <deal.II/grid/grid_refinement.h>
#include <deal.II/grid/tria.h>
#include <deal.II/grid/tria_accessor.h>
#include <deal.II/grid/tria_iterator.h>
#include <deal.II/lac/constraint_matrix.h>
#include <deal.II/lac/dynamic_sparsity_pattern.h>
#include <deal.II/lac/full_matrix.h>
#include <deal.II/lac/precondition.h>
#include <deal.II/lac/solver_bicgstab.h>
#include <deal.II/lac/sparse_matrix.h>
#include <deal.II/lac/vector.h>
#include <deal.II/numerics/data_out.h>
#include <deal.II/numerics/matrix_tools.h>
#include <deal.II/numerics/vector_tools.h>
```

The following two files provide classes and information for multithreaded programs. In the first one, the classes and functions are declared which we need to do assembly in parallel (i.e. the WorkStream namespace). The second file has a class MultithreadInfo which can be used to query the number of processors in your system, which is often useful when deciding how many threads to start in parallel.

```
#include <deal.II/base/multithread_info.h>
#include <deal.II/base/work_stream.h>
```

The next new include file declares a base class <code>TensorFunction</code> not unlike the <code>Function</code> class, but with the difference that the return value is tensor-valued rather than scalar of vector-valued.

```
#include <deal.II/base/tensor_function.h>
#include <deal.II/numerics/error_estimator.h>
```

### Ginkgo's header file

#include <ginkgo/ginkgo.hpp>

This is C++, as we want to write some output to disk:

```
#include <fstream>
#include <iostream>
```

### The last step is as in previous programs:

```
namespace Step9 {
using namespace dealii;
```

### AdvectionProblem class declaration

Following we declare the main class of this program. It is very much like the main classes of previous examples, so we again only comment on the differences.

```
template <int dim>
class AdvectionProblem {
public:
   AdvectionProblem();
   AdvectionProblem();
   void run();
private:
   void setup system();
```

The next set of functions will be used to assemble the matrix. However, unlike in the previous examples, the <code>assemble\_system()</code> function will not do the work itself, but rather will delegate the actual assembly to helper functions <code>assemble\_local\_system()</code> and <code>copy\_local\_to\_global()</code>. The rationale is that matrix assembly can be parallelized quite well, as the computation of the local contributions on each cell is entirely independent of other cells, and we only have to synchronize when we add the contribution of a cell to the global matrix.

The strategy for parallelization we choose here is one of the possibilities mentioned in detail in the threads module in the documentation. Specifically, we will use the WorkStream approach discussed there. Since there is so much documentation in this module, we will not repeat the rationale for the design choices here (for example, if you read through the module mentioned above, you will understand what the purpose of the <code>AssemblyScratchData</code> and <code>AssemblyCopyData</code> structures is). Rather, we will only discuss the specific implementation.

If you read the page mentioned above, you will find that in order to parallelize assembly, we need two data structures – one that corresponds to data that we need during local integration ("scratch data", i.e., things we only need as temporary storage), and one that carries information from the local integration to the function that then adds the local contributions to the corresponding elements of the global matrix. The former of these typically contains the FEValues and FEFaceValues objects, whereas the latter has the local matrix, local right hand side, and information about which degrees of freedom live on the cell for which we are assembling a local contribution. With this information, the following should be relatively self-explanatory:

```
struct AssemblyScratchData {
    AssemblyScratchData(const FiniteElement<dim> &fe);
    AssemblyScratchData(const AssemblyScratchData &scratch_data);
    FEValues<dim> fe_values;
    FEFaceValues<dim> fe_face_values;
};
struct AssemblyCopyData {
    FullMatrix<double> cell_matrix;
    Vector<double> cell_rhs;
    std::vector<types::global_dof_index> local_dof_indices;
};
void assemble_system();
void local_assemble_system(
    const typename DoFHandler<dim>::active_cell_iterator &cell,
    AssemblyScratchData &scratch, AssemblyCopyData &copy_data);
void copy_local_to_global(const AssemblyCopyData &copy_data);
```

The following functions again are as in previous examples, as are the subsequent variables.

```
void solve();
void refine_grid();
void output_results(const unsigned int cycle) const;
Triangulation<dim> triangulation;
DoFHandler<dim> dof_handler;
FE_Q<dim> fe;
ConstraintMatrix hanging_node_constraints;
SparsityPattern sparsity_pattern;
SparseMatrix<double> system_matrix;
Vector<double> solution;
Vector<double> system_rhs;
};
```

### **Equation data declaration**

Next we declare a class that describes the advection field. This, of course, is a vector field with as many components as there are space dimensions. One could now use a class derived from the Function base class, as we have done for boundary values and coefficients in previous examples, but there is another possibility in the library, namely

a base class that describes tensor valued functions. In contrast to the usual Function objects, we provide the compiler with knowledge on the size of the objects of the return type. This enables the compiler to generate efficient code, which is not so simple for usual vector-valued functions where memory has to be allocated on the heap (thus, the Function::vector\_value function has to be given the address of an object into which the result is to be written, in order to avoid copying and memory allocation and deallocation on the heap). In addition to the known size, it is possible not only to return vectors, but also tensors of higher rank; however, this is not very often requested by applications, to be honest...

The interface of the TensorFunction class is relatively close to that of the Function class, so there is probably no need to comment in detail the following declaration:

In previous examples, we have used assertions that throw exceptions in several places. However, we have never seen how such exceptions are declared. This can be done as follows:

The syntax may look a little strange, but is reasonable. The format is basically as follows: use the name of one of the macros DeclExceptionN, where N denotes the number of additional parameters which the exception object shall take. In this case, as we want to throw the exception when the sizes of two vectors differ, we need two arguments, so we use DeclException2. The first parameter then describes the name of the exception, while the following declare the data types of the parameters. The last argument is a sequence of output directives that will be piped into the std::cerr object, thus the strange format with the leading << operator and the like. Note that we can access the parameters which are passed to the exception upon construction (i.e. within the Assert call) by using the names arg1 through argN, where N is the number of arguments as defined by the use of the respective macro DeclExceptionN.

To learn how the preprocessor expands this macro into actual code, please refer to the documentation of the exception classes in the base library. Suffice it to say that by this macro call, the respective exception class is declared, which also has error output functions already implemented.

The following two functions implement the interface described above. The first simply implements the function as described in the introduction, while the second uses the same trick to avoid calling a virtual function as has already been introduced in the previous example program. Note the check for the right sizes of the arguments in the second function, which should always be present in such functions; it is our experience that many if not most programming errors result from incorrectly initialized arrays, incompatible parameters to functions and the like; using assertion as in this case can eliminate many of these problems.

Besides the advection field, we need two functions describing the source terms (right hand side) and the boundary values. First for the right hand side, which follows the same pattern as in previous examples. As described in the introduction, the source is a constant function in the vicinity of a source point, which we denote by the constant static variable center\_point. We set the values of this center using the same template tricks as we have shown

in the step-7 example program. The rest is simple and has been shown previously, including the way to avoid virtual function calls in the value\_list function.

The only new thing here is that we check for the value of the component parameter. As this is a scalar function, it is obvious that it only makes sense if the desired component has the index zero, so we assert that this is indeed the case. ExcIndexRange is a global predefined exception (probably the one most often used, we therefore made it global instead of local to some class), that takes three parameters: the index that is outside the allowed range, the first element of the valid range and the one past the last (i.e. again the half-open interval so often used in the C++ standard library):

Finally for the boundary values, which is just another class derived from the Function base class:

```
class BoundaryValues : public Function<dim> {
public:
    BoundaryValues() : Function<dim>() {}
    virtual double value(const Point<dim> &p,
                         const unsigned int component = 0) const;
    virtual void value_list(const std::vector<Point<dim> &points,
                            std::vector<double> &values,
                            const unsigned int component = 0) const;
template <int dim>
double BoundaryValues<dim>::value(const Point<dim> &p,
                                  const unsigned int component) const
    (void) component;
    Assert (component == 0, ExcIndexRange (component, 0, 1));
    const double sine term =
       std::sin(16 * numbers::PI * std::sqrt(p.norm_square()));
    const double weight = std::exp(-5 * p.norm_square()) / std::exp(-5.);
    return sine_term * weight;
template <int dim>
void BoundaryValues<dim>::value_list(const std::vector<Point<dim> &points,
                                     std::vector<double> &values,
                                     const unsigned int component) const
    Assert(values.size() == points.size(),
          ExcDimensionMismatch(values.size(), points.size()));
    for (unsigned int i = 0; i < points.size(); ++i)</pre>
        values[i] = BoundaryValues<dim>::value(points[i], component);
```

### **GradientEstimation class declaration**

Now, finally, here comes the class that will compute the difference approximation of the gradient on each cell and weighs that with a power of the mesh size, as described in the introduction. This class is a simple version of the DerivativeApproximation class in the library, that uses similar techniques to obtain finite difference approximations of the gradient of a finite element field, or of higher derivatives.

The class has one public static function <code>estimate</code> that is called to compute a vector of error indicators, and a few private functions that do the actual work on all active cells. As in other parts of the library, we follow an informal convention to use vectors of floats for error indicators rather than the common vectors of doubles, as the additional accuracy is not necessary for estimated values.

In addition to these two functions, the class declares two exceptions which are raised when a cell has no neighbors in each of the space directions (in which case the matrix described in the introduction would be singular and can't be inverted), while the other one is used in the more common case of invalid parameters to a function, namely a vector of wrong size.

Two other comments: first, the class has no non-static member functions or variables, so this is not really a class, but rather serves the purpose of a namespace in C++. The reason that we chose a class over a namespace is that this way we can declare functions that are private. This can be done with namespaces as well, if one declares some functions in header files in the namespace and implements these and other functions in the implementation file. The functions not declared in the header file are still in the namespace but are not callable from outside. However, as we have only one file here, it is not possible to hide functions in the present case.

The second comment is that the dimension template parameter is attached to the function rather than to the class itself. This way, you don't have to specify the template parameter yourself as in most other cases, but the compiler can figure its value out itself from the dimension of the DoF handler object that one passes as first argument.

Before jumping into the fray with the implementation, let us also comment on the parallelization strategy. We have already introduced the necessary framework for using the WorkStream concept in the declaration of the main class of this program above. We will use it again here. In the current context, this means that we have to define (i) classes for scratch and copy objects, (ii) a function that does the local computation on one cell, and (iii) a function that copies the local result into a global object. Given this general framework, we will, however, deviate from it a bit. In particular, WorkStream was generally invented for cases where each local computation on a cell adds to a global object - for example, when assembling linear systems where we add local contributions into a global matrix and right hand side. WorkStream is designed to handle the potential conflict of multiple threads trying to do this addition at the same time, and consequently has to provide for some way to ensure that only thread gets to do this at a time. Here, however, the situation is slightly different: we compute contributions from every cell individually, but then all we need to do is put them into an element of an output vector that is unique to each cell. Consequently, there is no risk that the write operations from two cells might conflict, and the elaborate machinery of WorkStream to avoid conflicting writes is not necessary. Consequently, what we will do is this: We still need a scratch object that holds, for example, the FEValues object. However, we only create a fake, empty copy data structure. Likewise, we do need the function that computes local contributions, but since it can already put the result into its final location, we do not need a copy-local-to-global function and will instead give the WorkStream::run() function an empty function object - the equivalent to a NULL function pointer.

```
class GradientEstimation {
    template <int dim>
    static void estimate(const DoFHandler<dim> &dof,
                           const Vector < double > & solution.
                           Vector<float> &error per cell);
    DeclException2(ExcInvalidVectorLength, int, int, "Vector has length " « arg1 « ", but should have "
                    « arg2);
    DeclException0(ExcInsufficientDirections);
private:
    template <int dim>
    struct EstimateScratchData {
        EstimateScratchData(const FiniteElement<dim> &fe,
                              const Vector<double> &solution,
                              Vector<float> &error_per_cell);
        EstimateScratchData (const EstimateScratchData &data);
        FEValues<dim> fe midpoint value;
        const Vector<double> &solution;
        Vector<float> &error_per_cell;
```

```
};
struct EstimateCopyData {};
template <int dim>
static void estimate_cell(
    const typename DoFHandler<dim>::active_cell_iterator &cell,
    EstimateScratchData<dim> &scratch_data,
    const EstimateCopyData &copy_data);
;
```

### AdvectionProblem class implementation

Now for the implementation of the main class. Constructor, destructor and the function <code>setup\_system</code> follow the same pattern that was used previously, so we need not comment on these three function:

```
template <int dim>
AdvectionProblem<dim>::AdvectionProblem() : dof_handler(triangulation), fe(1)
template <int dim>
AdvectionProblem < dim>:: AdvectionProblem ()
    dof handler.clear();
template <int dim>
void AdvectionProblem < dim > :: setup system ()
    dof_handler.distribute_dofs(fe);
    hanging node constraints.clear();
    DoFTools::make hanging node constraints(dof handler.
                                             hanging_node_constraints);
    hanging_node_constraints.close();
    DynamicSparsityPattern dsp(dof_handler.n_dofs(), dof_handler.n_dofs());
    DoFTools::make_sparsity_pattern(dof_handler, dsp, hanging_node_constraints,
                                      *keep_constrained_dofs = * / true);
    sparsity pattern.copy from(dsp);
    system matrix.reinit(sparsity pattern);
    solution.reinit(dof_handler.n_dofs());
    system_rhs.reinit(dof_handler.n_dofs());
```

In the following function, the matrix and right hand side are assembled. As stated in the documentation of the main class above, it does not do this itself, but rather delegates to the function following next, utilizing the WorkStream concept discussed in threads .

If you have looked through the threads module, you will have seen that assembling in parallel does not take an incredible amount of extra code as long as you diligently describe what the scratch and copy data objects are, and if you define suitable functions for the local assembly and the copy operation from local contributions to global objects. This done, the following will do all the heavy lifting to get these operations done on multiple threads on as many cores as you have in your system:

After the matrix has been assembled in parallel, we still have to eliminate hanging node constraints. This is something that can't be done on each of the threads separately, so we have to do it now. Note also, that unlike in previous examples, there are no boundary conditions to be applied to the system of equations. This, of course, is due to the fact that we have included them into the weak formulation of the problem.

```
hanging_node_constraints.condense(system_matrix);
hanging_node_constraints.condense(system_rhs);
```

As already mentioned above, we need to have scratch objects for the parallel computation of local contributions. These objects contain FEValues and FEFaceValues objects, and so we will need to have constructors and copy constructors that allow us to create them. In initializing them, note first that we use bilinear elements, soGauss formulae with two points in each space direction are sufficient. For the cell terms we need the values and gradients of the shape functions, the quadrature points in order to determine the source density and the advection field at a given point, and the weights of the quadrature points times the determinant of the Jacobian at these points. In contrast, for the boundary integrals, we don't need the gradients, but rather the normal vectors to the cells. This determines which update flags we will have to pass to the constructors of the members of the class:

```
template <int dim>
AdvectionProblem<dim>::AssemblyScratchData::AssemblyScratchData(
    const FiniteElement<dim> &fe)
    : fe_values(fe, QGauss<dim>(2),
               update_values | update_gradients | update_quadrature_points |
                   update JxW values),
      fe_face_values(fe, QGauss<dim - 1>(2),
                    update_values | update_quadrature_points |
                         update_JxW_values | update_normal_vectors)
template <int dim>
AdvectionProblem<dim>::AssemblyScratchData::AssemblyScratchData(
    const AssemblyScratchData &scratch data)
    : fe_values(scratch_data.fe_values.get_fe(),
                scratch_data.fe_values.get_quadrature(),
                update_values | update_gradients | update_quadrature_points |
                    update_JxW_values),
      fe_face_values(scratch_data.fe_face_values.get_fe(),
                    scratch_data.fe_face_values.get_quadrature(),
                     update_values | update_quadrature_points |
                         update_JxW_values | update_normal_vectors)
{ }
```

Now, this is the function that does the actual work. It is not very different from the assemble\_system functions of previous example programs, so we will again only comment on the differences. The mathematical stuff follows closely what we have said in the introduction.

There are a number of points worth mentioning here, though. The first one is that we have moved the FEValues and FEFaceValues objects into the ScratchData object. We have done so because the alternative would have been to simply create one every time we get into this function – i.e., on every cell. It now turns out that the FEValues classes were written with the explicit goal of moving everything that remains the same from cell to cell into the construction of the object, and only do as little work as possible in FEValues::reinit() whenever we move to a new cell. What this means is that it would be very expensive to create a new object of this kind in this function as we would have to do it for every cell – exactly the thing we wanted to avoid with the FEValues class. Instead, what we do is create it only once (or a small number of times) in the scratch objects and then re-use it as often as we can.

This begs the question of whether there are other objects we create in this function whose creation is expensive compared to its use. Indeed, at the top of the function, we declare all sorts of objects. The <code>AdvectionField</code>, <code>RightHandSide</code> and <code>BoundaryValues</code> do not cost much to create, so there is no harm here. However, allocating memory in creating the <code>rhs\_values</code> and similar variables below typically costs a significant amount of time, compared to just accessing the (temporary) values we store in them. Consequently, these would be candidates for moving into the <code>AssemblyScratchData</code> class. We will leave this as an exercise.

```
template <int dim>
void AdvectionProblem<dim>::local_assemble_system(
   const typename DoFHandler<dim>::active_cell_iterator &cell,
   AssemblyScratchData &scratch_data, AssemblyCopyData &copy_data)
{
```

First of all, we will need some objects that describe boundary values, right hand side function and the advection field. As we will only perform actions on these objects that do not change them, we declare them as constant, which can enable the compiler in some cases to perform additional optimizations.

```
const AdvectionField<dim> advection_field;
const RightHandSide<dim> right_hand_side;
const BoundaryValues<dim> boundary_values;
```

Then we define some abbreviations to avoid unnecessarily long lines:

```
const unsigned int dofs_per_cell = fe.dofs_per_cell;
const unsigned int n_q_points =
    scratch_data.fe_values.get_quadrature().size();
const unsigned int n_face_q_points =
    scratch_data.fe_face_values.get_quadrature().size();
```

We declare cell matrix and cell right hand side...

```
copy_data.cell_matrix.reinit(dofs_per_cell, dofs_per_cell);
copy_data.cell_rhs.reinit(dofs_per_cell);
```

... an array to hold the global indices of the degrees of freedom of the cell on which we are presently working...

... and array in which the values of right hand side, advection direction, and boundary values will be stored, for cell and face integrals respectively:

... and assemble the local contributions to the system matrix and right hand side as also discussed above:

Besides the cell terms which we have built up now, the bilinear form of the present problem also contains terms on the boundary of the domain. Therefore, we have to check whether any of the faces of this cell are on the boundary of the domain, and if so assemble the contributions of this face as well. Of course, the bilinear form only contains contributions from the inflow part of the boundary, but to find out whether a certain part of a face of the present cell is part of the inflow boundary, we have to have information on the exact location of the quadrature points and on the direction of flow at this point; we obtain this information using the FEFaceValues object and only decide within the main loop whether a quadrature point is on the inflow boundary.

Ok, this face of the present cell is on the boundary of the domain. Just as for the usual FEValues object which we have used in previous examples and also above, we have to reinitialize the FEFaceValues object for the present face:

```
scratch_data.fe_face_values.reinit(cell, face);
```

For the quadrature points at hand, we ask for the values of the inflow function and for the direction of flow:

```
boundary_values.value_list(
    scratch_data.fe_face_values.get_quadrature_points(),
    face_boundary_values);
advection_field.value_list(
    scratch_data.fe_face_values.get_quadrature_points(),
    face_advection_directions);
```

Now loop over all quadrature points and see whether it is on the inflow or outflow part of the boundary. This is determined by a test whether the advection direction points inwards or outwards of the domain (note that the normal vector points outwards of the cell, and since the cell is at the boundary, the normal vector points outward of the domain, so if the advection direction points into the domain, its scalar product with the normal vector must be negative):

If the is part of the inflow boundary, then compute the contributions of this face to the global matrix and right hand side, using the values obtained from the FEFaceValues object and the formulae discussed in the introduction:

```
for (unsigned int i = 0; i < dofs_per_cell; ++i) {</pre>
    for (unsigned int j = 0; j < dofs_per_cell; ++j)</pre>
         copy_data.cell_matrix(i, j) -
              (\texttt{face\_advection\_directions} \, [\, \underline{q} \, \underline{\hspace{1pt}} \, point \, ] \  \  \, \star
               scratch_data.fe_face_values.normal_vector(
                   a point) *
               scratch_data.fe_face_values.shape_value(
                   i, q_point)
               scratch_data.fe_face_values.shape_value(
                   j, q_point)
               scratch_data.fe_face_values.JxW(q_point));
    copy_data.cell_rhs(i) -=
         (face advection directions[g point] *
          scratch_data.fe_face_values.normal_vector(
              q_point) *
          face_boundary_values[q_point] *
          scratch_data.fe_face_values.shape_value(i,
                                                        q_point) *
          scratch_data.fe_face_values.JxW(q_point));
```

Now go on by transferring the local contributions to the system of equations into the global objects. The first step was to obtain the global indices of the degrees of freedom on this cell.

```
cell->get_dof_indices(copy_data.local_dof_indices);
```

The second function we needed to write was the one that copies the local contributions the previous function has computed and put into the copy data object, into the global matrix and right hand side vector objects. This is essentially what we always had as the last block of code when assembling something on every cell. The following should therefore be pretty obvious:

Following is the function that solves the linear system of equations. As the system is no more symmetric positive definite as in all the previous examples, we can't use the Conjugate Gradients method anymore. Rather, we use a solver that is tailored to nonsymmetric systems like the one at hand, the BiCGStab method. As preconditioner, we use the Block Jacobi method.

```
template <int dim>
void AdvectionProblem<dim>::solve()
{
```

### Assert that the system be symmetric.

```
Assert(system_matrix.m() == system_matrix.n(), ExcNotQuadratic());
auto num_rows = system_matrix.m();
```

### Make a copy of the rhs to use with Ginkgo.

```
std::vector<double> rhs(num_rows);
std::copy(system_rhs.begin(), system_rhs.begin() + num_rows, rhs.begin());
```

Ginkgo setup Some shortcuts: A vector is a Dense matrix with co-dimension 1. The matrix is setup in CSR. But various formats can be used. Look at Ginkgo's documentation.

```
using vec = gko::matrix::Dense<>;
using mtx = gko::matrix::Csr<>;
using bicgstab = gko::solver::Bicgstab<>;
using bj = gko::preconditioner::Jacobi<>;
using val_array = gko::Array<double>;
```

Where the code is to be executed. Can be changed to omp or cuda to run on multiple threads or on gpu's std::shared\_ptr<gko::Executor> exec = gko::ReferenceExecutor::create();

### Setup Ginkgo's data structures

```
system_matrix.n_nonzero_elements());
mtx::value_type *values = A->get_values();
mtx::index_type *row_ptr = A->get_row_ptrs();
mtx::index_type *col_idx = A->get_col_idxs();
```

Convert to standard CSR format As deal.ii does not expose its system matrix pointers, we construct them individually

#### write entry into the first free one for this row

```
col_idx[ptrs[row]] = p->column();
values[ptrs[row]] = p->value();
```

### then move pointer ahead

```
++ptrs[row];
}
```

Ginkgo solve The stopping criteria is set at maximum iterations of 1000 and a reduction factor of 1e-12. For other options, refer to Ginkgo's documentation.

### Solve system

solver->apply(gko::lend(b), gko::lend(x));

Copy the solution vector back to deal.ii's data structures.

### Give the solution back to deall.ii

```
hanging_node_constraints.distribute(solution);
```

The following function refines the grid according to the quantity described in the introduction. The respective computations are made in the class <code>GradientEstimation</code>. The only difference to previous examples is that we refine a little more aggressively (0.5 instead of 0.3 of the number of cells).

Writing output to disk is done in the same way as in the previous examples. Indeed, the function is identical to the one in step-6.

```
template <int dim>
```

```
void AdvectionProblem<dim>::output_results(const unsigned int cycle) const
        GridOut grid out;
        std::ofstream output("grid-" + std::to_string(cycle) + ".eps");
        grid_out.write_eps(triangulation, output);
        DataOut<dim> data_out;
        data_out.attach_dof_handler(dof_handler);
        data_out.add_data_vector(solution, "solution");
        data_out.build_patches();
        std::ofstream output("solution-" + std::to_string(cycle) + ".vtk");
        data_out.write_vtk(output);
}
... as is the main loop (setup – solve – refine)
template <int dim>
void AdvectionProblem < dim >:: run ()
    for (unsigned int cycle = 0; cycle < 6; ++cycle) {
   std::cout « "Cycle " « cycle « ':' « std::endl;
   if (cycle == 0) {</pre>
             GridGenerator::hyper_cube(triangulation, -1, 1);
             triangulation.refine_global(4);
             refine_grid();
        std::cout « " Number of active cells:
                   « triangulation.n_active_cells() « std::endl;
        setup_system();
        std::cout « "
                          Number of degrees of freedom: " « dof_handler.n_dofs()
                   « std::endl;
        assemble_system();
        solve();
        output_results(cycle);
```

### **GradientEstimation class implementation**

Now for the implementation of the GradientEstimation class. Let us start by defining constructors for the EstimateScratchData class used by the estimate\_cell() function:

```
template <int dim>
GradientEstimation::EstimateScratchData<dim>::EstimateScratchData(
    const FiniteElement<dim> &fe, const Vector<double> &solution,
    Vector<float> &error_per_cell)
    : fe_midpoint_value(fe, QMidpoint<dim>(),
                        update_values | update_quadrature_points),
      solution(solution),
      error_per_cell(error_per_cell)
{ }
template <int dim>
GradientEstimation::EstimateScratchData<dim>::EstimateScratchData(
    const EstimateScratchData &scratch_data)
    : fe_midpoint_value(scratch_data.fe_midpoint_value.get_fe(),
                        scratch_data.fe_midpoint_value.get_quadrature(),
                        update_values | update_quadrature_points),
      solution(scratch_data.solution),
      error_per_cell(scratch_data.error_per_cell)
{ }
```

Next for the implementation of the <code>GradientEstimation</code> class. The first function does not much except for delegating work to the other function, but there is a bit of setup at the top.

Before starting with the work, we check that the vector into which the results are written has the right size. Programming mistakes in which one forgets to size arguments correctly at the calling site are quite common. Because the resulting damage from not catching such errors is often subtle (e.g., corruption of data somewhere in memory, or non-reproducible results), it is well worth the effort to check for such things.

Following now the function that actually computes the finite difference approximation to the gradient. The general outline of the function is to first compute the list of active neighbors of the present cell and then compute the quantities described in the introduction for each of the neighbors. The reason for this order is that it is not a one-liner to find a given neighbor with locally refined meshes. In principle, an optimized implementation would find neighbors and the quantities depending on them in one step, rather than first building a list of neighbors and in a second step their contributions but we will gladly leave this as an exercise. As discussed before, the worker function passed to WorkStream::run works on "scratch" objects that keep all temporary objects. This way, we do not need to create and initialize objects that are expensive to initialize within the function that does the work, every time it is called for a given cell. Such an argument is passed as the second argument. The third argument would be a "copy-data" object (see threads for more information) but we do not actually use any of these here. Because WorkStream::run() insists on passing three arguments, we declare this function with three arguments, but simply ignore the last one.

(This is unsatisfactory from an esthetic perspective. It can be avoided, at the cost of some other trickery. If you allow, let us here show how. First, assume that we had declared this function to only take two arguments by omitting the unused last one. Now, WorkStream::run still wants to call this function with three arguments, so we need to find a way to "forget" the third argument in the call. Simply passing WorkStream::run the pointer to the function as we do above will not do this – the compiler will complain that a function declared to have two arguments is called with three arguments. However, we can do this by passing the following as the third argument when calling WorkStream::run() above:

This creates a function object taking three arguments, but when it calls the underlying function object, it simply only uses the first and second argument – we simply "forget" to use the third argument :-) In the end, this isn't completely obvious either, and so we didn't implement it, but hey – it can be done!)

### Now for the details:

We need space for the tensor Y, which is the sum of outer products of the y-vectors.

Tensor<2, dim> Y;

Then we allocate a vector to hold iterators to all active neighbors of a cell. We reserve the maximal number of active neighbors in order to avoid later reallocations. Note how this maximal number of active neighbors is computed here.

## First initialize the FEValues object, as well as the Y tensor:

```
scratch_data.fe_midpoint_value.reinit(cell);
```

Then allocate the vector that will be the sum over the y-vectors times the approximate directional derivative:

Tensor<1, dim> projected gradient;

Now before going on first compute a list of all active neighbors of the present cell. We do so by first looping over all faces and see whether the neighbor there is active, which would be the case if it is on the same level as the present

cell or one level coarser (note that a neighbor can only be once coarser than the present cell, as we only allow a maximal difference of one refinement over a face in deal.II). Alternatively, the neighbor could be on the same level and be further refined; then we have to find which of its children are next to the present cell and select these (note that if a child of a neighbor of an active cell that is next to this active cell, needs necessarily be active itself, due to the one-refinement rule cited above).

Things are slightly different in one space dimension, as there the one-refinement rule does not exist: neighboring active cells may differ in as many refinement levels as they like. In this case, the computation becomes a little more difficult, but we will explain this below.

Before starting the loop over all neighbors of the present cell, we have to clear the array storing the iterators to the active neighbors, of course.

First define an abbreviation for the iterator to the face and the neighbor

```
const typename DoFHandler<dim>::face_iterator face =
   cell->face(face_no);
const typename DoFHandler<dim>::cell_iterator neighbor =
   cell->neighbor(face_no);
```

Then check whether the neighbor is active. If it is, then it is on the same level or one level coarser (if we are not in 1D), and we are interested in it in any case.

```
if (neighbor->active())
    active_neighbors.push_back(neighbor);
else {
```

If the neighbor is not active, then check its children.

```
if (dim == 1) {
```

To find the child of the neighbor which bounds to the present cell, successively go to its right child if we are left of the present cell (n==0), or go to the left child if we are on the right (n==1), until we find an active cell.

```
typename DoFHandler<dim>::cell_iterator neighbor_child =
    neighbor;
while (neighbor_child=>has_children())
    neighbor_child =
        neighbor_child->child(face_no == 0 ? 1 : 0);
```

As this used some non-trivial geometrical intuition, we might want to check whether we did it right, i.e. check whether the neighbor of the cell we found is indeed the cell we are presently working on. Checks like this are often useful and have frequently uncovered errors both in algorithms like the line above (where it is simple to involuntarily exchange n=1 for n=0 or the like) and in the library (the assumptions underlying the algorithm above could either be wrong, wrongly documented, or are violated due to an error in the library). One could in principle remove such checks after the program works for some time, but it might be a good things to leave it in anyway to check for changes in the library or in the algorithm above.

Note that if this check fails, then this is certainly an error that is irrecoverable and probably qualifies as an internal error. We therefore use a predefined exception class to throw here.

```
Assert(
  neighbor_child->neighbor(face_no == 0 ? 1 : 0) == cell,
  ExcInternalError());
```

If the check succeeded, we push the active neighbor we just found to the stack we keep:

```
active_neighbors.push_back(neighbor_child);
} else
```

If we are not in 1d, we collect all neighbor children 'behind' the subfaces of the current face

OK, now that we have all the neighbors, lets start the computation on each of them. First we do some preliminaries: find out about the center of the present cell and the solution at this point. The latter is obtained as a vector of

function values at the quadrature points, of which there are only one, of course. Likewise, the position of the center is the position of the first (and only) quadrature point in real space.

Now loop over all active neighbors and collect the data we need. Allocate a vector just like this\_midpoint\_  $\leftarrow$  value which we will use to store the value of the solution in the midpoint of the neighbor cell. We allocate it here already, since that way we don't have to allocate memory repeatedly in each iteration of this inner loop (memory allocation is a rather expensive operation):

```
std::vector<double> neighbor_midpoint_value(1);
typename std::vector<typename DoFHandler<dim>::active_cell_iterator>::
    const_iterator neighbor_ptr = active_neighbors.begin();
for (; neighbor_ptr != active_neighbors.end(); ++neighbor_ptr) {
```

First define an abbreviation for the iterator to the active neighbor cell:

```
const typename DoFHandler<dim>::active_cell_iterator neighbor =
   *neighbor_ptr;
```

Then get the center of the neighbor cell and the value of the finite element function thereon. Note that for this information we have to reinitialize the FEValues object for the neighbor cell.

```
scratch_data.fe_midpoint_value.reinit(neighbor);
const Point<dim> neighbor_center =
    scratch_data.fe_midpoint_value.quadrature_point(0);
scratch_data.fe_midpoint_value.get_function_values(
    scratch_data.solution, neighbor_midpoint_value);
```

Compute the vector y connecting the centers of the two cells. Note that as opposed to the introduction, we denote by y the normalized difference vector, as this is the quantity used everywhere in the computations.

Tensor<1, dim> y = neighbor\_center - this\_center;

```
const double distance = y.norm();
y /= distance;

Then add up the contribution of this cell to the Y matrix...
for (unsigned int i = 0; i < dim; ++i)
    for (unsigned int j = 0; j < dim; ++j) Y[i][j] += y[i] * y[j];

... and update the sum of difference quotients:
    projected_gradient +=</pre>
```

(neighbor\_midpoint\_value[0] - this\_midpoint\_value[0]) / distance \*

If now, after collecting all the information from the neighbors, we can determine an approximation of the gradient for the present cell, then we need to have passed over vectors y which span the whole space, otherwise we would not have all components of the gradient. This is indicated by the invertibility of the matrix.

If the matrix should not be invertible, this means that the present cell had an insufficient number of active neighbors. In contrast to all previous cases, where we raised exceptions, this is, however, not a programming error: it is a runtime error that can happen in optimized mode even if it ran well in debug mode, so it is reasonable to try to catch this error also in optimized mode. For this case, there is the AssertThrow macro: it checks the condition like the Assert macro, but not only in debug mode; it then outputs an error message, but instead of terminating the program as in the case of the Assert macro, the exception is thrown using the throw command of C++. This way, one has the possibility to catch this error and take reasonable counter actions. One such measure would be to refine the grid globally, as the case of insufficient directions can not occur if every cell of the initial grid has been refined at least once.

```
AssertThrow(determinant(Y) != 0, ExcInsufficientDirections());
```

If, on the other hand the matrix is invertible, then invert it, multiply the other quantity with it and compute the estimated error using this quantity and the right powers of the mesh width:

```
const Tensor<2, dim> Y_inverse = invert(Y);
Tensor<1, dim> gradient = Y_inverse * projected_gradient;
```

The last part of this function is the one where we write into the element of the output vector what we have just computed. The address of this vector has been stored in the scratch data object, and all we have to do is know how to get at the correct element inside this vector – but we can ask the cell we're on the how-manyth active cell it is for this:

```
scratch_data.error_per_cell(cell->active_cell_index()) =
    (std::pow(cell->diameter(), 1 + 1.0 * dim / 2) *
        std::sqrt(gradient.norm_square()));
// namespace Step9
```

#### **Main function**

The main function is similar to the previous examples. The main difference is that we use MultithreadInfo to set the maximum number of threads (see Parallel computing with multiple processors accessing shared memory" documentation module for more explanation). The number of threads used is the minimum of the environment variable DEAL\_II\_NUM\_THREADS and the parameter of set\_thread\_limit. If no value is given to set thread\_limit, the default value from the Intel Threading Building Blocks (TBB) library is used. If the call to set\_thread\_limit is omitted, the number of threads will be chosen by TBB indepently of DEAL\_II\_NUM\_T HREADS.

```
int main()
        dealii::MultithreadInfo::set thread limit();
        Step9::AdvectionProblem<2> advection_problem_2d;
        advection_problem_2d.run();
    } catch (std::exception &exc) {
        std::cerr « std::endl
                   « std::endl
« "-----
                   « std::endl;
        std::cerr « "Exception on processing: " « std::endl
                   « exc.what() « std::endl
« "Aborting!" « std::endl
                   « "-
                   « std::endl;
        return 1:
    } catch (...) {
        std::cerr « std::endl
                   « std::endl
                   « std::endl;
        std::cerr « "Unknown exception!" « std::endl
                   « "Aborting!" « std::endl
                   « std::endl;
        return 1;
    return 0:
```

# The ginkgo-ranges program

The ranges and accessor example..

## Introduction

About the example

## The commented program

```
#include <ginkgo/ginkgo.hpp>
#include <iomanip>
#include <iostream>
```

LU factorization implementation using Ginkgo ranges For simplicity, we only consider square matrices, and no pivoting.

```
template <typename Accessor> void factorize(const gko::range<Accessor> &A)
```

note: const means that the range (i.e. the data handler) is constant, not that the underlying data is constant!

```
dssing gko::span;
assert(A.length(0) == A.length(1));
for (gko::size_type i = 0; i < A.length(0) - 1; ++i) {
    const auto trail = span{i + 1, A.length(0)};</pre>
```

note: neither of the lines below need additional memory to store intermediate arrays, all computation is done at the point of assignment

```
A(trail, i) = A(trail, i) / A(i, i);
```

a utility function for printing the factorization on screen

```
template <typename Accessor>
void print_lu(const gko::range<Accessor> &A)
{
    std::cout « std::setprecision(2) « std::fixed;
    std::cout « "L = [";
    for (int i = 0; i < A.length(0); ++i) {
        std::cout « "\n ";
        for (int j = 0; j < A.length(1); ++j) {
            std::cout « (i > j ? A(i, j) : (i == j) * 1.) « " ";
        }
    }
    std::cout « "\n]\n\nU = [";
```

```
for (int i = 0; i < A.length(0); ++i) {
    std::cout « "\n ";
    for (int j = 0; j < A.length(1); ++j) {
        std::cout « (i <= j ? A(i, j) : 0.) « " ";
    }
} std::cout « "\n]" « std::endl;
}
int main(int argc, char *argv[])
{</pre>
```

#### Print version information

std::cout « gko::version\_info::get() « std::endl;

Create some test data, add some padding just to demonstrate how to use it with ranges. clang-format off

```
double data[] = {
    2., 4., 5., -1.0,
    4., 11., 12., -1.0,
    6., 24., 24., -1.0
}
```

clang-format on

Create a 3-by-3 range, with a 2D row-major accessor using data as the underlying storage. Set the stride (a.k.a. "I DA") to 4

```
auto A = gko::range<gko::accessor::row_major<double, 2>>(data, 3u, 3u, 4u);
```

use the LU factorization routine defined above to factorize the matrix factorize(A);

```
print the factorization on screen
    print_lu(A);
```

#### Results

This is the expected output:

```
L = [

1.00 0.00 0.00

2.00 1.00 0.00

3.00 4.00 1.00

]

U = [

2.00 4.00 5.00

0.00 3.00 2.00

0.00 0.00 1.00
```

      factorize(A);
     print_lu(A);
```

# The ilu-preconditioned-solver program

The ILU-preconditioned solver example..

This example depends on simple-solver.

### Introduction

#### About the example

This example shows how to use incomplete factors generated via the ParlLU algorithm to generate an incomplete factorization (ILU) preconditioner, how to specify the sparse triangular solves in the ILU preconditioner application, and how to generate an ILU-preconditioned solver and apply it to a specific problem.

## The commented program

```
#include <ginkgo/ginkgo.hpp>
#include <cstdlib>
#include <fstream>
#include <iostream>
#include <string>
int main(int argc, char *argv[])
Some shortcuts
using vec = gko::matrix::Dense<>;
using mtx = gko::matrix::Csr<>;
using gmres = gko::solver::Gmres<>;
Print version information
std::cout « gko::version_info::get() « std::endl;
Figure out where to run the code
std::shared_ptr<gko::Executor> exec;
if (argc == 1 || std::string(argv[1]) == "reference") {
    exec = gko::ReferenceExecutor::create();
} else if (argc == 2 && std::string(argv[1]) == "omp") {
    exec = gko::OmpExecutor::create();
}
} else if (argc == 2 && std::string(argv[1]) == "cuda" &&
              gko::CudaExecutor::get_num_devices() > 0) {
     exec = gko::CudaExecutor::create(0, gko::OmpExecutor::create());
} else {
     std::cerr « "Usage: " « argv[0] « " [executor]" « std::endl;
     std::exit(-1);
```

#### Read data

```
auto A = gko::share(gko::read<mtx>(std::ifstream("data/A.mtx"), exec));
auto b = gko::read<vec>(std::ifstream("data/b.mtx"), exec);
auto x = gko::read<vec>(std::ifstream("data/x0.mtx"), exec);
```

#### Generate incomplete factors using ParILU

```
auto par_ilu_fact = gko::factorization::ParIlu<>::build().on(exec);
```

#### Generate concrete factorization for input matrix

```
auto par_ilu = par_ilu_fact->generate(A);
```

Generate an ILU preconditioner factory by setting lower and upper triangular solver - in this case the exact triangular solves

#### Use incomplete factors to generate ILU preconditioner

```
auto ilu_preconditioner = ilu_pre_factory->generate(gko::share(par_ilu));
```

Use preconditioner inside GMRES solver factory Generating a solver factory tied to a specific preconditioner makes sense if there are several very similar systems to solve, and the same solver+preconditioner combination is expected to be effective.

#### Generate preconditioned solver for a specific target system

```
auto ilu_gmres = ilu_gmres_factory->generate(A);
```

#### Solve system

```
ilu_gmres->apply(gko::lend(b), gko::lend(x));
```

#### Print solution

```
std::cout « "Solution (x): \n";
write(std::cout, gko::lend(x));
```

#### Calculate residual

```
auto one = gko::initialize<vec>({1.0}, exec);
auto neg_one = gko::initialize<vec>({-1.0}, exec);
auto res = gko::initialize<vec>({0.0}, exec);
A->apply(gko::lend(one), gko::lend(x), gko::lend(neg_one), gko::lend(b));
b->compute_norm2(gko::lend(res));
std::cout « "Residual norm sqrt(r^T r): \n";
write(std::cout, gko::lend(res));
```

#### Results

#### This is the expected output:

# The inverse-iteration program

The inverse iteration example..

This example depends on simple-solver, .

### Introduction

This example shows how components available in Ginkgo can be used to implement higher-level numerical methods. The method used here will be the shifted inverse iteration method for eigenvalue computation which find the eigenvalue and eigenvector of A closest to z, for some scalar z. The method requires repeatedly solving the shifted linear system (A - zI)x = b, as well as performing matrix-vector products with the matrix A. Here is the complete pseudocode of the method:

#### About the example

## The commented program

```
#include <ginkgo/ginkgo.hpp>
#include <cmath>
#include <complex>
#include <fstream>
#include <ioonanip>
#include <string>
int main(int argc, char *argv[]) {

Some shortcuts

using precision = std::complex<double>;
using real_precision = double;
using vec = gko::matrix::Denseprecision>;
using solver_type = gko::solver::Bicgstabprecision>;
using std::abs;
using std::sqrt;
```

#### Print version information

```
std::cout « gko::version_info::get() « std::endl;
```

```
std::cout « std::scientific « std::setprecision(8) « std::showpos;
```

#### Figure out where to run the code

#### linear system solver parameters

```
auto system_max_iterations = 100u;
auto system_residual_goal = real_precision{1e-16};
```

#### eigensolver parameters

```
auto max_iterations = 20u;
auto residual_goal = real_precision(1e-8);
auto z = precision(20.0, 2.0);
```

#### Read data

```
auto A = share(gko::read<mtx>(std::ifstream("data/A.mtx"), exec));
```

#### Generate shifted matrix A - zI

we avoid duplicating memory by not storing both A and A - zI, but compute A - zI on the fly by using Ginkgo's
utilities for creating linear combinations of operators

```
auto one = share(gko::initialize<vec>({precision{1.0}}, exec));
auto neg_one = share(gko::initialize<vec>({-precision{1.0}}, exec));
auto neg_z = gko::initialize<vec>({-z}, exec);
auto system_matrix = share(gko::Combination<precision>::create(
    one, A, gko::initialize<vec>({-z}, exec),
    gko::matrix::Identity<precision>::create(exec, A->get_size()[0])));
```

#### Generate solver operator (A - zl)^-1

#### inverse iterations

```
start with guess [1, 1, ..., 1]
```

x->compute\_norm2(lend(norm));

```
auto x = [&] {
    auto work = vec::create(this_exec, gko::dim<2>{A->get_size()[0], 1});
    const auto n = work->get_size()[0];
    for (int i = 0; i < n; ++i) {
        work->get_values()[i] = precision{1.0} / sqrt(n);
    }
    return clone(exec, work);
}();
auto y = clone(x);
auto tmp = clone(x);
auto norm = clone(one);
auto inv_norm = clone(this_exec, one);
auto g = clone(one);
for (auto i = 0u; i < max_iterations; ++i) {
    std::cout « "{ ";
}

(A - zl)y = X
solver->apply(lend(x), lend(y));
```

system\_matrix->apply(lend(one), lend(y), lend(neg\_one), lend(x));

```
std::cout « "\"system_residual\": "
             « clone(this_exec, norm)->get_values()[0] « ", ";
x->copy_from(lend(y));
x = y / || y ||
x->compute_norm2(lend(norm));
inv_norm->get_values()[0] =
     precision{1.0} / clone(this_exec, norm)->get_values()[0];
x->scale(lend(clone(exec, inv norm)));
q = x^* A x
A->apply(lend(x), lend(tmp));
x->compute_dot(lend(tmp), lend(g));
auto g_val = clone(this_exec, g)->get_values()[0];
std::cout « "\"eigenvalue\": " « g_val « ", ";
||Ax - gx|| < tol * g
          auto v = gko::initialize<vec>({-q_val}, exec);
          tmp->add_scaled(lend(v), lend(x));
          tmp->compute_norm2(lend(norm));
          auto res_val = clone(exec->get_master(), norm)->get_values()[0];
std::cout « "\"residual\": " « res_val / g_val « " }," « std::endl;
          if (abs(res_val) < residual_goal * abs(g_val)) {</pre>
               break;
```

#### This is the expected output:

# The minimal-cuda-solver program

The minimal CUDA solver example..

This example depends on simple-solver.

### Introduction

This is a minimal example that solves a system with Ginkgo. The matrix, right hand side and initial guess are read from standard input, and the result is written to standard output. The system matrix is stored in CSR format, and the system solved using the CG method, preconditioned with the block-Jacobi preconditioner. All computations are done on the GPU.

The easiest way to use the example data from the data/ folder is to concatenate the matrix, the right hand side and the initial solution (in that exact order), and pipe the result to the minimal\_solver\_cuda executable:

cat data/A.mtx data/b.mtx data/x0.mtx | ./minimal\_solver\_cuda

#### About the example

### The commented program

```
#include <ginkgo/ginkgo.hpp>
#include <iostream>
int main()
Instantiate a CUDA executor
auto gpu = gko::CudaExecutor::create(0, gko::OmpExecutor::create());
auto A = gko::read<gko::matrix::Csr<»(std::cin, gpu);
auto b = gko::read<gko::matrix::Dense<»(std::cin, gpu);</pre>
auto x = gko::read<gko::matrix::Dense<>(std::cin, gpu);
Create the solver
auto solver =
    gko::solver::Cg<>::build()
        .with_preconditioner(gko::preconditioner::Jacobi<>::build().on(gpu))
             gko::stop::Iteration::build().with_max_iters(20u).on(gpu),
             gko::stop::ResidualNormReduction<>::build()
                .with_reduction_factor(1e-15)
                  .on(gpu))
         .on(gpu);
Solve system
solver->generate(give(A))->apply(lend(b), lend(x));
Write result
    write(std::cout, lend(x));
```

The following is the expected result when using the data contained in the folder data as input:

```
%%MatrixMarket matrix array real general

# The nine-pt-stencil-solver program

The 9-point stencil example..

This example depends on simple-solver, three-pt-stencil-solver, poisson-solver.

#### Introduction

This example solves a 2D Poisson equation:

[  $\Omega = (0,1)^2 \ D = [0,1]^2 \ U = (0,1)^2 \ U = (0,1)^2$ 

using a finite difference method on an equidistant grid with K discretization points (K can be controlled with a command line parameter). The discretization may be done by any order Taylor polynomial. For an equidistant grid with K "inner" discretization points ((x1,y1), \ldots, (xk,y1),(x1,y2), \ldots, (xk,yk,z1)) step size (h = 1 / (K + 1)) and a stencil (\in \mathb{R}^{3} \times 3), the formula produces a system of linear equations

 $(\sum_{a,b=-1}^{1} stencil(a,b) * u_{(i+a,j+b)} = -f_k h^2)$ , on any inner node with a neighborhood of inner nodes

On any node, where neighbor is on the border, the neighbor is replaced with a (-stencil(a,b) \* u\_{i+a,j+b}) and added to the right hand side vector. For example a node with a neighborhood of only edge nodes may look like this

```
[\sum_{a,b=-1}^{(1,0)} stencil(a,b) * u_{(i+a,j+b)} = -f_k h^2 - \sum_{a=-1}^{1} stencil(a,1) * u_{(i+a,j+1)}]
```

which is then solved using Ginkgo's implementation of the CG method preconditioned with block-Jacobi. It is also possible to specify on which executor Ginkgo will solve the system via the command line. The function f is set to (f(x,y) = 6x + 6y) (making the solution  $(u(x,y) = x^3)$ 

• y<sup>3</sup>)), but that can be changed in the main function. Also the stencil values for the core, the faces, the edge and the corners can be changed when passing additional parameters.

The intention of this is to show how generation of stencil values and the right hand side vector changes when increasing the dimension.

#### About the example

## The commented program

```
*****CDESCRIPTION>******************
This example solves a 2D Poisson equation:
     \langle Omega = (0,1)^2
     \Omega = [0,1]^2
                            (with boundary)
     \partial\Omega = \Omega_b \backslash \Omega
    u : \Omega_b -> R
u" = f in \Omega
     u = u_D on \partial\Omega
using a finite difference method on an equidistant grid with 'K' discretization
points ('K' can be controlled with a command line parameter). The discretization
may be done by any order Taylor polynomial.
For an equidistant grid with K "inner" discretization points (x1,y1),
(xk,y1), (x1,y2), ..., (xk,yk) step size h=1 / (K+1) and a stencil \in
\R^{3 \times 3}, the formula produces a system of linear equations
\sum_{a,b=-1}^1 \text{stencil}(a,b) * u_{(i+a,j+b)} = -f_k h^2, on any inner node with
a neighborhood of inner nodes
On any node, where neighbor is on the border, the neighbor is replaced with a '-stencil(a,b) * u_{i}-ta,j+b)' and added to the right hand side vector. For
example a node with a neighborhood of only edge nodes may look like this
\sum_{a,b=-1}^{(1,0)} stencil(a,b) * u_{(i+a,j+b)} = -f_k h^2 - \sum_{a=-1}^{1} stance{-1}
stencil(a,1) * u_{(i+a,j+1)
which is then solved using Ginkgo's implementation of the CG method
preconditioned with block-Jacobi. It is also possible to specify on which
executor Ginkgo will solve the system via the command line. The function 'f' is set to 'f(x,y) = 6x + 6y' (making the solution 'u(x,y) = x^3 + y^3'), but that can be changed in the 'main' function. Also the stencil values
for the core, the faces, the edge and the corners can be changed when passing
additional parameters.
The intention of this is to show how generation of stencil values and the right
hand side vector changes when increasing the dimension.
            #include <array>
#include <chrono>
#include <ginkgo/ginkgo.hpp>
#include <iostream>
#include <map>
#include <string>
#include <vector>
```

Stencil values. Ordering can be seen in the main function Can also be changed by passing additional parameter when executing

```
constexpr double default_alpha = 10.0 / 3.0;
constexpr double default_beta = -2.0 / 3.0;
constexpr double default_gamma = -1.0 / 6.0;
/ * Possible alternative default values are for example
* default_alpha = 8.0;
* default_beta = -1.0;
* default_gamma = -1.0;
* /
```

Creates a stencil matrix in CSR format for the given number of discretization points.

```
Generates the RHS vector given f and the boundary conditions.
```

```
template <typename Closure, typename ClosureT>
void generate_rhs(int dp, Closure f, ClosureT u, double *rhs, double *coefs)
{
   const size_t dp_2 = dp * dp;
   const auto h = 1.0 / (dp + 1.0);
   for (int i = 0; i < dp; ++i) {
      const auto yi = (i + 1) * h;
      for (int j = 0; j < dp; ++j) {
       const auto xi = (j + 1) * h;
      const auto index = i * dp + j;
      rhs[index] = -f(xi, yi) * h * h;
   }
}</pre>
```

Iterating over the edges to add boundary values and adding the overlapping 3x1 to the rhs

```
for (size_t i = 0; i < dp; ++i) {
    const auto xi = (i + 1) * h;
    const auto index_top = i;
    const auto index_bot = i + dp * (dp - 1);
    rhs[index_top] -= u(xi - h, 0.0) * coefs[0];
    rhs[index_top] -= u(xi, 0.0) * coefs[1];
    rhs[index_top] -= u(xi - h, 0.0) * coefs[2];
    rhs[index_bot] -= u(xi - h, 1.0) * coefs[2];
    rhs[index_bot] -= u(xi - h, 1.0) * coefs[7];
    rhs[index_bot] -= u(xi + h, 1.0) * coefs[7];
    rhs[index_bot] -= u(xi + h, 1.0) * coefs[8];
}
for (size_t i = 0; i < dp; ++i) {
    const auto yi = (i + 1) * h;
    const auto index_left = i * dp;
    const auto index_right = i * dp + (dp - 1);
    rhs[index_left] -= u(0.0, yi - h) * coefs[0];
    rhs[index_left] -= u(0.0, yi + h) * coefs[6];
    rhs[index_right] -= u(1.0, yi - h) * coefs[2];
    rhs[index_right] -= u(1.0, yi + h) * coefs[5];
    rhs[index_right] -= u(1.0, yi + h) * coefs[8];
}</pre>
```

#### remove the double corner values

```
rhs[0] += u(0.0, 0.0) * coefs[0];
rhs[(dp - 1)] += u(1.0, 0.0) * coefs[2];
rhs[(dp - 1) * dp] += u(0.0, 1.0) * coefs[6];
rhs[dp * dp - 1] += u(1.0, 1.0) * coefs[8];
```

#### Prints the solution u.

```
void print_solution(int dp, const double *u)
{
    for (int i = 0; i < dp; ++i) {
        for (int j = 0; j < dp; ++j) {
            std::cout « u[i * dp + j] « ' ';
        }
        std::cout « '\n';
    }
    std::cout « std::endl;
}</pre>
```

Computes the 1-norm of the error given the computed u and the correct solution function  $\mathtt{correct\_u}.$ 

```
template <typename Closure>
double calculate_error(int dp, const double *u, Closure correct_u)
     const auto h = 1.0 / (dp + 1);
     auto error = 0.0;
    for (int j = 0; j < dp; ++j) {
   const auto xi = (j + 1) * h;
   for (int i = 0; i < dp; ++i) {</pre>
              using std::abs;
               const auto yi = (i + 1) * h;
               error +=
                    abs\left(u\left[i \ \star \ dp \ + \ j\right] \ - \ correct\_u\left(xi, \ yi\right)\right) \ / \ abs\left(correct\_u\left(xi, \ yi\right)\right);
          }
     return error;
void solve_system(const std::string &executor_string,
                       unsigned int discretization_points, int *row_ptrs,
                       int *col_idxs, double *values, double *rhs, double *u,
                       double accuracy)
{
```

#### Some shortcuts

Tell Ginkgo to use the data in our application

const auto app exec = exec map["omp"];

Matrix: we have to set the executor of the matrix to the one where we want SpMVs to run (in this case exec). When creating array views, we have to specify the executor where the data is (in this case app\_exec).

If the two do not match, Ginkgo will automatically create a copy of the data on exec (however, it will not copy the data back once it is done

· here this is not important since we are not modifying the matrix).

Solution: we have to be careful here - if the executors are different, once we compute the solution the array will not be automatically copied back to the original memory locations. Fortunately, whenever  $\mathtt{apply}$  is called on a linear operator (e.g. matrix, solver) the arguments automatically get copied to the executor where the operator is, and copied back once the operation is completed. Thus, in this case, we can just define the solution on  $\mathtt{app\_exec}$ , and it will be automatically transferred to/from  $\mathtt{exec}$  if needed.

```
Generate solver
auto solver_gen :
   cq::build()
       .with criteria(
          gko::stop::Iteration::build().with_max_iters(dp_2).on(exec),
           gko::stop::ResidualNormReduction<>::build()
              .with_reduction_factor(accuracy)
              .on(exec))
       .with_preconditioner(bj::build().on(exec))
       .on(exec);
auto solver = solver_gen->generate(gko::give(matrix));
Solve system
   solver->apply(gko::lend(b), gko::lend(x));
int main(int argc, char *argv[])
       std::cerr « "Usage: " « argv[0] « " DISCRETIZATION_POINTS [executor]"
                « " [stencil_alpha] [stencil_beta] [stencil_gamma]'
                « std::endl;
       std::exit(-1);
```

```
const int discretization_points = argc >= 2 ? std::atoi(argv[1]) : 100;

This example solves a 2D Poisson equation:
           \Omega = (0,1)^2
            Omega_b = [0,1]^2 (with boundary)
           \partial\Omega = \Omega_b \backslash \Omega
          u:\Omega_b -> R
u" = f in \Omega
          u = u_D on \operatorname{partial}\operatorname{Omega}
using a finite difference method on an equidistant grid with 'K' discretization
points ('K' can be controlled with a command line parameter). The discretization
may be done by any order Taylor polynomial. For an equidistant grid with K "inner" discretization points (x1,y1),
 (xk,y1), (x1,y2), ..., (xk,yk) step size h=1 / (K+1) and a stencil \in
 \R^{3} x 3}, the formula produces a system of linear equations
\sum_{a,b=-1}^1 \text{ stencil}(a,b) * u_{(i+a,j+b)} = -f_k h^2, \text{ on any inner node with } 
a neighborhood of inner nodes
On any node, where neighbor is on the border, the neighbor is replaced with a '-stencil(a,b) * u_{i}-ta,j+b)' and added to the right hand side vector. For
example a node with a neighborhood of only edge nodes may look like this
\sum_{a,b=-1}^{1} (1,0)  stencil(a,b) * u_{(i+a,j+b)} = -f_k h^2 - \sum_{a=-1}^1
stencil(a,1) * u_{(i+a,j+1)}
which is then solved using Ginkgo's implementation of the CG method
preconditioned with block-Jacobi. It is also possible to specify on which
executor Ginkgo will solve the system via the command line. The function 'f' is set to 'f(x,y) = 6x + 6y' (making the solution 'u(x,y) = x^3 + y^3'), but that can be changed in the 'main' function. Also the stencil values
for the core, the faces, the edge and the corners can be changed when passing
additional parameters.
The intention of this is to show how generation of stencil values and the right
hand side vector changes when increasing the dimension.

    std::ostringstream os;
    os « reinterpret_cast<gko::uintptr>(ptr);
    return os.str();
int init_papi_counters(std::string solver_name, std::string A_name)
Initialize PAPI, add events and start it up
    int eventset = PAPI_NULL;
int ret_val = PAPI_library_init(PAPI_VER_CURRENT);
    if (ret_val != PAPI_VER_CURRENT) {
        std::cerr « "Error at PAPI_library_init()" « std::endl;
        std::exit(-1);
    ret_val = PAPI_create_eventset(&eventset);
```

```
if (PAPI_OK != ret_val) {
          std::cerr « "Error at PAPI_create_eventset()" « std::endl;
          std::exit(-1);
     std::string simple_apply_string("sde:::ginkgo0::linop_apply_completed::");
     std::string advanced_apply_string(
    "sde:::ginkgo0::linop_advanced_apply_completed::");
     papi_add_event(simple_apply_string + solver_name, eventset);
papi_add_event(simple_apply_string + A_name, eventset);
     papi_add_event(advanced_apply_string + A_name, eventset);
     ret_val = PAPI_start(eventset);
     if (PAPI_OK != ret_val) {
   std::cerr « "Error at PAPI_start()" « std::endl;
          std::exit(-1);
     return eventset;
void print_papi_counters(int eventset)
Stop PAPI and read the linop_apply_completed event for all of them
long long int values[3];
int ret_val = PAPI_stop(eventset, values);
if (PAPI_OK != ret_val) {
     std::cerr « "Error at PAPI_stop()" « std::endl;
     std::exit(-1);
PAPI shutdown();
Print all values returned from PAPI
     sd::cout « "PAPI SDE counters:" « std::endl;
std::cout « "solver did " « values[0] « " applies." « std::endl;
std::cout « "A did " « values[1] « " simple applies." « std::endl;
std::cout « "A did " « values[2] « " advanced applies." « std::endl;
int main(int argc, char *argv[])
Some shortcuts
using vec = gko::matrix::Dense<>;
using mtx = gko::matrix::Csr<>;
using cg = gko::solver::Cg<>;
Print version information
std::cout « gko::version_info::get() « std::endl;
Figure out where to run the code
std::shared_ptr<gko::Executor> exec;
if (argc == 1 || std::string(argv[1]) == "reference") {
     exec = gko::ReferenceExecutor::create();
} else if (argc == 2 && std::string(argv[1]) == "omp") {
    exec = gko::OmpExecutor::create();
} else if (argc == 2 && std::string(argv[1]) == "cuda" &&
              gko::CudaExecutor::get_num_devices() > 0) {
     exec = gko::CudaExecutor::create(0, gko::OmpExecutor::create());
} else {
     std::cerr « "Usage: " « argv[0] « " [executor]" « std::endl;
     std::exit(-1);
Read data
auto A = share(gko::read<mtx>(std::ifstream("data/A.mtx"), exec));
auto b = gko::read<wcc/(std::ifstream("data/A.mtx"), exec);
auto x = gko::read<vec>(std::ifstream("data/x0.mtx"), exec);
Generate solver
auto solver gen =
     cg::build()
          .with_criteria(
               gko::stop::Iteration::build().with_max_iters(20u).on(exec),
                gko::stop::ResidualNormReduction<>::build()
                     .with_reduction_factor(1e-20)
                     .on(exec))
           .on(exec);
auto solver = solver_gen->generate(A);
```

In this example, we split as much as possible the Ginkgo solver/logger and the PAPI interface. Note that the PAPI ginkgo namespaces are of the form sde:::ginkgo<x> where <x> starts from 0 and is incremented with every new PAPI logger.

```
int eventset =
    init_papi_counters(to_string(solver.get()), to_string(A.get()));
Create a PAPI logger and add it to relevant LinOps
auto logger = gko::log::Papi<>::create(
    exec, gko::log::Logger::linop_apply_completed_mask |
              gko::log::Logger::linop_advanced_apply_completed_mask);
solver->add_logger(logger);
A->add_logger(logger);
Solve system
solver->apply(lend(b), lend(x));
Stop PAPI event gathering and print the counters
print_papi_counters(eventset);
Print solution
std::cout « "Solution (x): \n";
write(std::cout, lend(x));
Calculate residual
    auto one = gko::initialize<vec>({1.0}, exec);
    auto neg_one = gko::initialize<vec>((-1.0), exec);
    auto res = gko::initialize<vec>((0.0), exec);
    A->apply(lend(one), lend(x), lend(neg_one), lend(b));
    b->compute_norm2(lend(res));
std::cout « "Residual norm sqrt(r^T r): \n";
    write(std::cout, lend(res));
```

## The following is the expected result:

```
PAPI SDE counters: solver did 1 applies.
A did 20 simple applies.
A did 1 advanced applies.

  // namespace utils
namespace loggers {
```

A logger that accumulates the time of all operations. For each operation type (allocations, free, copy, internal operations i.e. kernels), the timing is taken before and after. This can create significant overhead since to ensure proper timings, calls to synchronize are required.

```
struct OperationLogger : gko::log::Logger {
   void on_allocation_started(const gko::Executor *exec,
                              const gko::size_type &) const override
       this->start_operation(exec, "allocate");
   void on_allocation_completed(const gko::Executor *exec,
                                const gko::size_type &,
                                const gko::uintptr &) const override
       this->end_operation(exec, "allocate");
   void on_free_started(const gko::Executor *exec,
                        const gko::uintptr &) const override
       this->start operation(exec, "free");
   void on_free_completed(const gko::Executor *exec,
                          const gko::uintptr &) const override
       this->end_operation(exec, "free");
   void on_copy_started(const gko::Executor *from, const gko::Executor *to,
                       const gko::uintptr &, const gko::uintptr &,
                        const gko::size_type &) const override
       from->synchronize();
       this->start_operation(to, "copy");
   void on_copy_completed(const gko::Executor *from, const gko::Executor *to,
                         const gko::uintptr &, const gko::uintptr &,
                          const gko::size_type &) const override
       from->synchronize();
       this->end_operation(to, "copy");
   void on_operation_launched(const gko::Executor *exec,
                              const gko::Operation *op) const override
       this->start_operation(exec, op->get_name());
   void on_operation_completed(const gko::Executor *exec,
                               const gko::Operation *op) const override
       this->end_operation(exec, op->get_name());
   void write_data(std::ostream &ostream)
       for (const auto &entry : total) {
           ostream « "\t" « entry.first.c_str() « ": "
                   « std::chrono::duration_cast<std::chrono::nanoseconds>(
                          entry.second)
                          .count()
                   « std::endl;
       }
```

Helper which synchronizes and starts the time before every operation.

Helper to compute the end time and store the operation's time at its end. Also time nested operations.

```
void end_operation(const gko::Executor *exec, const std::string &name) const
{
    exec->synchronize();
    const auto end = std::chrono::steady_clock::now();
    const auto diff = end - start[name];
```

make sure timings for nested operations are not counted twice

```
total[name] += diff - nested.back();
nested.pop_back();
if (nested.size() > 0) {
    nested.back() += diff;
}
mutable std::map<std::string, std::chrono::steady_clock::time_point> start;
mutable std::map<std::string, std::chrono::steady_clock::duration> total;
```

the position i of this vector holds the total time spend on child operations on nesting level i

```
mutable std::vector<std::chrono::steady_clock::duration> nested;
```

#### This logger tracks the persistently allocated data

struct StorageLogger : gko::log::Logger {

### Store amount of bytes allocated on every allocation

## Reset the amount of bytes on every free

### Write the data after summing the total from all allocations

```

Parametrize the benchmark here Pick a value type
using vtype = double;
Pick a matrix format
using mtx = gko::matrix::Csr<vtype>;
Pick a solver
using solver = gko::solver::Cg<vtype>;
Pick a preconditioner type
using preconditioner = gko::matrix::IdentityFactory<vtype>;
```

```
Pick a residual norm reduction value
```

```
auto reduction_factor = 1e-8;
```

#### Pick a maximum iteration count

```
auto max_iters = 2000u;
```

#### Pick an output file name

```
auto of_name = "log.txt";
```

#### Simple shortcut

```
using vec = gko::matrix::Dense<vtype>;
```

#### Print version information

```
std::cout « gko::version_info::get() « std::endl;
```

#### Figure out where to run the code

#### Read the input matrix file directory

```
std::string input_mtx = "data/A.mtx";
if (argc == 3) {
    input_mtx = std::string(argv[2]);
}
```

#### Read data: A is read from disk Create a StorageLogger to track the size of A

auto storage\_logger = std::make\_shared<loggers::StorageLogger>(exec);

#### Add the logger to the executor

exec->add\_logger(storage\_logger);

#### Read the matrix A from file

```
auto A = gko::share(gko::read<mtx>(std::ifstream(input_mtx), exec));
```

## Remove the storage logger

exec->remove\_logger(gko::lend(storage\_logger));

#### Generate b and x vectors

```
auto b = utils::create_vector<vtype>(exec, A->get_size()[0], 1.0); auto x = utils::create_vector<vtype>(exec, A->get_size()[0], 0.0);
```

#### Declare the solver factory. The preconditioner's arguments should be adapted if needed.

## Declare the output file for all our loggers

```
std::ofstream output_file(of_name);
```

# Do a warmup run

{

#### Clone x to not overwrite the original one

```
auto x_clone = gko::clone(x);
```

### Generate and call apply on a solver

```
solver_factory->generate(A)->apply(gko::lend(b), gko::lend(x_clone));
    exec->synchronize();
Do a timed run
Clone x to not overwrite the original one
auto x_clone = gko::clone(x);
Synchronize ensures no operation are ongoing
exec->synchronize();
Time before generate
auto g_tic = std::chrono::steady_clock::now();
Generate a solver
auto generated_solver = solver_factory->generate(A);
exec->synchronize();
Time after generate
auto g_tac = std::chrono::steady_clock::now();
Compute the generation time
auto generate_time
    std::chrono::duration_cast<std::chrono::nanoseconds>(g_tac - g_tic);
Write the generate time to the output file
output_file « "Generate time (ns): " « generate_time.count()
            « std::endl;
Similarly time the apply
exec->synchronize();
auto a_tic = std::chrono::steady_clock::now();
\verb|generated_solver->apply(gko::lend(b), gko::lend(x_clone));|\\
exec->synchronize();
auto a_tac = std::chrono::steady_clock::now();
auto apply_time
std::chrono::duration_cast<std::chrono::nanoseconds>(a_tac - a_tic);
output_file « "Apply time (ns): " « apply_time.count() « std::endl;
Compute the residual norm
    auto residual = utils::compute_residual_norm(gko::lend(A), gko::lend(b),
    output_file « "Residual_norm: " « residual « std::endl;
Log the internal operations using the OperationLogger without timing
Clone x to not overwrite the original one
auto x clone = gko::clone(x);
Create an OperationLogger to analyze the generate step
auto gen_logger = std::make_shared<loggers::OperationLogger>(exec);
Add the generate logger to the executor
exec->add_logger(gen_logger);
Generate a solver
auto generated_solver = solver_factory->generate(A);
Remove the generate logger from the executor
exec->remove_logger(gko::lend(gen_logger));
Write the data to the output file
output_file « "Generate operations times (ns):" « std::endl;
gen_logger->write_data(output_file);
```

Create an OperationLogger to analyze the apply step

```
auto apply_logger = std::make_shared<loggers::OperationLogger>(exec);
exec->add_logger(apply_logger);
Create a ResidualLogger to log the recurent residual
auto res_logger = std::make_shared<loggers::ResidualLogger<vtype»(
    exec, gko::lend(A), gko::lend(b));</pre>
generated_solver->add_logger(res_logger);
Solve the system
generated_solver->apply(gko::lend(b), gko::lend(x_clone));
exec->remove_logger(gko::lend(apply_logger));
Write the data to the output file
    output_file « "Apply operations times (ns):" « std::endl;
    apply_logger->write_data(output_file);
    res_logger->write_data(output_file);
Print solution
std::cout « "Solution, first ten entries: \n";
print_vector(gko::lend(x));
Print output file location
    std::cout « "The performance and residual data can be found in " « of_name
               « std::endl;
```

#### This is the expected standard output:

# The poisson-solver program

The poisson solver example..

This example depends on simple-solver.

### Introduction

This example solves a 1D Poisson equation:

$$u:[0,1]\rightarrow R$$

$$u"=f$$

$$u(0)=u0$$

$$u(1)=u1$$

using a finite difference method on an equidistant grid with  $\mathbb K$  discretization points ( $\mathbb K$  can be controlled with a command line parameter). The discretization is done via the second order Taylor polynomial:

For an equidistant grid with K "inner" discretization points x1,...,xk,and step size h=1/(K+1), the formula produces a system of linear equations

$$2u_1 - u_2 = -f_1h^2 + u0$$
  
-  $u(k-1) + 2u_k - u(k+1) = -f_kh^2, k = 2, ..., K-1$   
-  $u(K-1) + 2u_K = -f_Kh^2 + u1$ 

which is then solved using Ginkgo's implementation of the CG method preconditioned with block-Jacobi. It is also possible to specify on which executor Ginkgo will solve the system via the command line. The function 'f'is set to 'f(x) = 6x' (making the solution ' $u(x) = x^3$ '), but that can be changed in the main function.

The intention of the example is to show how Ginkgo can be used to build an application solving a real-world problem, which includes a solution of a large, sparse linear system as a component.

#### About the example

# The commented program

```
#include <ginkgo/ginkgo.hpp>
#include <iostream>
#include <map>
#include <string>
#include <vector>

Creates a stencil matrix in CS
void generate_stencil_matrix {
```

Creates a stencil matrix in CSR format for the given number of discretization points.

```
void generate_stencil_matrix(gko::matrix::Csr<> *matrix)
{
   const auto discretization_points = matrix->get_size()[0];
   auto row_ptrs = matrix->get_row_ptrs();
   auto col_idxs = matrix->get_col_idxs();
   auto values = matrix->get_values();
   int pos = 0;
   const double coefs[] = {-1, 2, -1};
   row_ptrs[0] = pos;
   for (int i = 0; i < discretization_points; ++i) {
      for (auto ofs : {-1, 0, 1}) {
         if (0 <= i + ofs && i + ofs < discretization_points) {
            values[pos] = coefs[ofs + 1];
            col_idxs[pos] = i + ofs;
            ++pos;
         }
        row_ptrs[i + 1] = pos;
    }
}</pre>
```

#### Generates the RHS vector given f and the boundary conditions.

```
template <typename Closure>
void generate_rhs(Closure f, double u0, double u1, gko::matrix::Dense<> *rhs)
{
   const auto discretization_points = rhs->get_size()[0];
   auto values = rhs->get_values();
   const auto h = 1.0 / (discretization_points + 1);
   for (int i = 0; i < discretization_points; ++i) {
      const auto xi = (i + 1) * h;
      values[i] = -f(xi) * h * h;
   }
   values[0] += u0;
   values[discretization_points - 1] += u1;
}</pre>
```

### Prints the solution u.

```
void print_solution(double u0, double u1, const gko::matrix::Dense<> *u)
{
    std::cout « u0 « '\n';
    for (int i = 0; i < u->get_size()[0]; ++i) {
        std::cout « u->get_const_values()[i] « '\n';
    }
    std::cout « u1 « std::endl;
}
```

Computes the 1-norm of the error given the computed u and the correct solution function correct\_u.

#### Some shortcuts

```
using vec = gko::matrix::Dense<double>;
using mtx = gko::matrix::Csr<double, int>;
using cg = gko::solver::Cg<double>;
using bj = gko::preconditioner::Jacobi<>;
```

```
if (argc < 2) {</pre>
    std::cerr « "Usage: " « argv[0] « " DISCRETIZATION_POINTS [executor]"
                « std::endl;
     std::exit(-1);
Get number of discretization points
const unsigned int discretization_points =
   argc >= 2 ? std::atoi(argv[1]) : 100;
const auto executor_string = argc >= 3 ? argv[2] : "reference";
Figure out where to run the code
const auto omp = gko::OmpExecutor::create();
std::map<std::string, std::shared_ptr<gko::Executor» exec_map{
     {"omp", omp}, {"cuda", gko::CudaExecutor::create(0, omp)},
     {"reference", gko::ReferenceExecutor::create()}};
executor where Ginkgo will perform the computation
const auto exec = exec_map.at(executor_string); // throws if not valid
executor used by the application
const auto app_exec = exec_map["omp"];
problem:
auto correct_u = [](double x) { return x * x * x; };
auto f = [](double x) { return 6 * x; };
auto u0 = correct_u(0);
auto u1 = correct_u(1);
initialize matrix and vectors
auto matrix = mtx::create(app_exec, gko::dim<2>(discretization_points),
                              3 * discretization_points - 2);
generate_stencil_matrix(lend(matrix));
auto rhs = vec::create(app_exec, gko::dim<2>(discretization_points, 1));
generate_rhs(f, u0, u1, lend(rhs));
auto u = vec::create(app_exec, gko::dim<2>(discretization_points, 1));
for (int i = 0; i < u->get_size()[0]; ++i) {
    u->get_values()[i] = 0.0;
}
Generate solver and solve the system
         .with_criteria(gko::stop::Iteration::build()
                               .with_max_iters(discretization_points)

# The preconditioned-solver program

The preconditioned solver example..

This example depends on simple-solver.

### Introduction

#### About the example

# The commented program

```
#include <ginkgo/ginkgo.hpp>
#include <fstream>
#include <iostream>
#include <string>
int main(int argc, char *argv[])
Some shortcuts
using vec = gko::matrix::Dense<>;
using mtx = gko::matrix::Csr<>;
using cg = gko::solver::Cg<>;
using bj = gko::preconditioner::Jacobi<>;
Print version information
std::cout « gko::version_info::get() « std::endl;
Figure out where to run the code
std::shared_ptr<gko::Executor> exec;
if (argc == 1 || std::string(argv[1]) == "reference") {
     exec = gko::ReferenceExecutor::create();
} else if (argc == 2 && std::string(argv[1]) == "omp") {
    exec = gko::OmpExecutor::create();
} else if (argc == 2 && std::string(argv[1]) == "cuda" &&
     gko::CudaExecutor::get_num_devices() > 0) {
  exec = gko::CudaExecutor::create(), gko::OmpExecutor::create());
     std::cerr « "Usage: " « argv[0] « " [executor]" « std::endl;
     std::exit(-1);
Read data
auto A = share(gko::read<mtx>(std::ifstream("data/A.mtx"), exec));
auto b = gko::read<vec>(std::ifstream("data/b.mtx"), exec);
auto x = gko::read<vec>(std::ifstream("data/x0.mtx"), exec);
```

## Create solver factory

```
auto solver_gen =
    cg::build()
         .with_criteria(
              gko::stop::Iteration::build().with_max_iters(20u).on(exec),
              gko::stop::ResidualNormReduction<>::build()
                   .with_reduction_factor(1e-20)
                   .on(exec))
Add preconditioner, these 2 lines are the only difference from the simple solver example
.with_preconditioner(bj::build().with_max_block_size(8u).on(exec))
.on(exec);
Create solver
auto solver = solver_gen->generate(A);
Solve system
solver->apply(lend(b), lend(x));
Print solution
std::cout « "Solution (x): n";
write(std::cout, lend(x));
Calculate residual
     auto one = gko::initialize<vec>({1.0}, exec);
     auto neg_one = gko::initialize<vec>({-1.0}, exec);
auto res = gko::initialize<vec>({0.0}, exec);
    A->apply(lend(one), lend(x), lend(neg_one), lend(b));
b->compute_norm2(lend(res));
std::cout « "Residual norm sqrt(r^T r): \n";
     write(std::cout, lend(res));
```

#### This is the expected output:

```

# The simple-solver program

The simple solver example..

## Introduction

This simple solver example should help you get started with Ginkgo. This example is meant for you to understand how Ginkgo works and how you can solve a simple linear system with Ginkgo. We encourage you to play with the code, change the parameters and see what is best suited for your purposes.

## About the example

Each example has the following sections:

- 1. **Introduction:**This gives an overview of the example and mentions any interesting aspects in the example that might help the reader.
- 2. **The commented program:** This section is intended for you to understand the details of the example so that you can play with it and understand Ginkgo and its features better.
- 3. **Results:** This section shows the results of the code when run. Though the results may not be completely the same, you can expect the behaviour to be similar.
- 4. **The plain program:** This is the complete code without any comments to have an complete overview of the code.

# The commented program

#### Include files

This is the main ginkgo header file.

#include <ginkgo/ginkgo.hpp>

Add the fstream header to read from data from files.

#include <fstream>

Add the C++ iostream header to output information to the console.

```
#include <iostream
```

Add the string manipulation header to handle strings.

```
#include <string>
int main(int argc, char *argv[])
{
```

Use some shortcuts. In Ginkgo, vectors are seen as a gko::matrix::Dense with one column/one row. The advantage of this concept is that using multiple vectors is a now a natural extension of adding columns/rows are necessary.

using vec = gko::matrix::Dense<>;

The gko::matrix::Csr class is used here, but any other matrix class such as gko::matrix::Coo, gko::matrix::Hybrid, gko::matrix::Ell or gko::matrix::Sellp could also be used.

```
using mtx = gko::matrix::Csr<>;
```

The gko::solver::Cg is used here, but any other solver class can also be used.

```
using cg = gko::solver::Cg<>;
```

#### Print the ginkgo version information.

```
std::cout « gko::version_info::get() « std::endl;
```

#### Where do you want to run your solver?

The gko::Executor class is one of the cornerstones of Ginkgo. Currently, we have support for an gko::OmpExecutor, which uses OpenMP multi-threading in most of its kernels, a gko::ReferenceExecutor, a single threaded specialization of the OpenMP executor and a gko::CudaExecutor which runs the code on a NVIDIA GPU if available.

#### Note

With the help of C++, you see that you only ever need to change the executor and all the other functions/routines within Ginkgo should automatically work and run on the executor with any other changes.

#### Reading your data and transfer to the proper device.

Read the matrix, right hand side and the initial solution using the read function.

#### Note

Ginkgo uses C++ smart pointers to automatically manage memory. To this end, we use our own object ownership transfer functions that under the hood call the required smart pointer functions to manage object ownership. The gko::share, gko::give and gko::lend are the functions that you would need to use.

```
auto A = share(gko::read<mtx>(std::ifstream("data/A.mtx"), exec));
auto b = gko::read<vec>(std::ifstream("data/b.mtx"), exec);
auto x = gko::read<vec>(std::ifstream("data/x0.mtx"), exec);
```

#### Creating the solver

Generate the gko::solver factory. Ginkgo uses the concept of Factories to build solvers with certain properties. Observe the Fluent interface used here. Here a cg solver is generated with a stopping criteria of maximum iterations of 20 and a residual norm reduction of 1e-15. You also observe that the stopping criteria(gko::stop) are also generated from factories using their build methods. You need to specify the executors which each of the object needs to be built on.

Generate the solver from the matrix. The solver factory built in the previous step takes a "matrix" (a gko::LinOp to be more general) as an input. In this case we provide it with a full matrix that we previously read, but as the solver only effectively uses the apply() method within the provided "matrix" object, you can effectively create a gko::LinOp class with your own apply implementation to accomplish more tasks. We will see an example of how this can be done in the custom-matrix-format example

```
auto solver = solver_gen->generate(A);
```

Finally, solve the system. The solver, being a gko::LinOp, can be applied to a right hand side, b to obtain the solution, x.

```
solver->apply(lend(b), lend(x));
```

Print the solution to the command line.

```
std::cout « "Solution (x): \n";
write(std::cout, lend(x));
```

To measure if your solution has actually converged, you can measure the error of the solution. one, neg\_one are objects that represent the numbers which allow for a uniform interface when computing on any device. To compute the residual, all you need to do is call the apply method, which in this case is an spmv and equivalent to the LAPACK z spmv routine. Finally, you compute the euclidean 2-norm with the compute norm2 function.

```
auto one = gko::initialize<vec>({1.0}, exec);
auto neg_one = gko::initialize<vec>({-1.0}, exec);
auto res = gko::initialize<vec>({0.0}, exec);
A->apply(lend(one), lend(x), lend(neg_one), lend(b));
b->compute_norm2(lend(res));
std::cout « "Residual norm sqrt(r^T r): \n";
write(std::cout, lend(res));
```

## Results

The following is the expected result:

```
Solution (x):
%%MatrixMarket matrix array real general

# The simple-solver-logging program

The simple solver with logging example..

This example depends on simple-solver, minimal-cuda-solver.

### Introduction

About the example

# The commented program

```
#include <ginkgo/ginkgo.hpp>
#include <fstream>
#include <iomanip>
#include <iostream>
#include <string>
void print_vector(const std::string &name, const gko::matrix::Dense<> *vec)
    std::cout « name « " = [" « std::endl;
    for (int i = 0; i < vec->get_size()[0]; ++i) {
    std::cout « " " « vec->at(i, 0) « std::endl;
    std::cout « "];" « std::endl;
   // namespace
int main(int argc, char *argv[])
Some shortcuts
using vec = gko::matrix::Dense<>;
using mtx = gko::matrix::Csr<>;
using cg = gko::solver::Cg<>;
Print version information
std::cout « gko::version_info::get() « std::endl;
Figure out where to run the code
std::shared_ptr<gko::Executor> exec;
if (argc == 1 || std::string(argv[1]) == "reference") {
    exec = gko::ReferenceExecutor::create();
} else if (argc == 2 && std::string(argv[1]) == "omp") {
   exec = gko::OmpExecutor::create();
} else if (argc == 2 && std::string(argv[1]) == "cuda" &&
           gko::CudaExecutor::get_num_devices() > 0) {
    exec = gko::CudaExecutor::create(0, gko::OmpExecutor::create());
} else {
   std::cerr « "Usage: " « argv[0] « " [executor]" « std::endl;
    std::exit(-1);
```

}

#### Read data

```
auto A = share(gko::read<mtx>(std::ifstream("data/A.mtx"), exec));
auto b = gko::read<vec>(std::ifstream("data/b.mtx"), exec);
auto x = gko::read<vec>(std::ifstream("data/x0.mtx"), exec);
```

Let's declare a logger which prints to std::cout instead of printing to a file. We log all events except for all linop factory and polymorphic object events. Events masks are group of events which are provided for convenience.

#### Add stream\_logger to the executor

exec->add\_logger(stream\_logger);

Add stream\_logger only to the ResidualNormReduction criterion Factory Note that the logger will get automatically propagated to every criterion generated from this factory.

#### Generate solver

```
auto solver_gen =
   cg::build()
    .with_criteria(
        residual_criterion,
        gko::stop::Iteration::build().with_max_iters(20u).on(exec))
    .on(exec);
auto solver = solver_gen->generate(A);
```

First we add facilities to only print to a file. It's possible to select events, using masks, e.g. only iterations mask: gko::log::Logger::iteration\_complete\_mask. See the documentation of Logger class for more information.

```
std::ofstream filestream("my_file.txt");
solver->add_logger(gko::log::Stream<>::create(
    exec, gko::log::Logger::all_events_mask, filestream));
solver->add_logger(stream_logger);
```

Add another logger which puts all the data in an object, we can later retrieve this object in our code. Here we only have want Executor and criterion check completed events.

### Solve system

solver->apply(lend(b), lend(x));

Finally, get some data from record\_logger and print the last memory location copied

Also print the residual of the last criterion check event (where convergence happened)

```
auto residual =
    record_logger->get().criterion_check_completed.back()->residual.get();
auto residual_d = gko::as<gko::matrix::Dense<»(residual);
print_vector("Residual", residual_d);</pre>
```

#### Print solution

```
std::cout « "Solution (x): \n";
write(std::cout, lend(x));
```

#### Calculate residual

```
auto one = gko::initialize<vec>({1.0}, exec);
auto neg_one = gko::initialize<vec>({-1.0}, exec);
auto res = gko::initialize<vec>({0.0}, exec);
A->apply(lend(one), lend(x), lend(neg_one), lend(b));
b->compute_norm2(lend(res));
std::cout « "Residual norm sqrt(r^T r): \n";
write(std::cout, lend(res));
```

```
This is the expected output:

# **Chapter 22**

# The three-pt-stencil-solver program

The 3-point stencil example..

This example depends on simple-solver, poisson-solver.

## Introduction

This example solves a 1D Poisson equation:

$$u: [0,1] \rightarrow R$$

$$u'' = f$$

$$u(0) = u0$$

$$u(1) = u1$$

using a finite difference method on an equidistant grid with K discretization points (K can be controlled with a command line parameter). The discretization is done via the second order Taylor polynomial:

For an equidistant grid with K "inner" discretization points x1,...,xk,and step size h=1/(K+1), the formula produces a system of linear equations

$$2u_1 - u_2 = -f_1h^2 + u0$$
  
-  $u_(k-1) + 2u_k - u_(k+1) = -f_kh^2, k = 2, ..., K-1$   
-  $u_(K-1) + 2u_K = -f_Kh^2 + u1$ 

which is then solved using Ginkgo's implementation of the CG method preconditioned with block-Jacobi. It is also possible to specify on which executor Ginkgo will solve the system via the command line. The function 'f'is set to 'f(x) = 6x' (making the solution ' $u(x) = x^3$ '), but that can be changed in the main function.

The intention of the example is to show how Ginkgo can be integrated into existing software - the <code>generate</code>—<code>stencil\_matrix</code>, <code>generate\_rhs</code>, <code>print\_solution</code>, <code>compute\_error</code> and <code>main</code> function do not reference Ginkgo at all (i.e. they could have been there before the application developer decided to use Ginkgo, and the only part where Ginkgo is introduced is inside the <code>solve\_system</code> function.

#### About the example

# The commented program

This example solves a 1D Poisson equation:

```
u : [0, 1] -> R
u" = f
     u(0) = u0
     u(1) = u1
using a finite difference method on an equidistant grid with 'K' discretization
points ('K' can be controlled with a command line parameter). The discretization
is done via the second order Taylor polynomial:
u(x + h) = u(x) - u'(x)h + 1/2 u'(x)h^2 + 0(h^3)

u(x - h) = u(x) + u'(x)h + 1/2 u''(x)h^2 + 0(h^3)
-u(x - h) + 2u(x) + -u(x + h) = -f(x)h^2 + O(h^3)
For an equidistant grid with K "inner" discretization points x1, ..., xk, and
step size h=1 / (K + 1), the formula produces a system of linear equations 2u_1 - u_2 = -f_1 h^2 + u0
-u_{k-1} + 2u_{k} - u_{k+1} = -f_{k} h^2,

-u_{k-1} + 2u_{k} = -f_{k} h^2 + u_{k+1}
                                                      k = 2, ..., K - 1
-u_(K-1) + 2u_K
which is then solved using Ginkgo's implementation of the CG method
preconditioned with block-Jacobi. It is also possible to specify on which executor Ginkgo will solve the system via the command line. The function 'f' is set to 'f(x) = 6x' (making the solution 'u(x) = x^3'), but
that can be changed in the 'main' function.
The intention of the example is to show how Ginkgo can be integrated into existing software - the 'generate_stencil_matrix', 'generate_rhs', 'print_solution', 'compute_error' and 'main' function do not reference Ginkgo at
all (i.e. they could have been there before the application developer decided to
use Ginkgo, and the only part where Ginkgo is introduced is inside the
'solve_system' function.
#include <ginkgo/ginkgo.hpp>
#include <iostream>
#include <map>
#include <string>
#include <vector>
Creates a stencil matrix in CSR format for the given number of discretization points.
void generate_stencil_matrix(int discretization_points, int *row_ptrs,
                                   int *col_idxs, double *values)
     int pos = 0;
     const double coefs[] = \{-1, 2, -1\};
     row_ptrs[0] = pos;
for (int i = 0; i < discretization_points; ++i) {</pre>
          for (auto ofs : {-1, 0, 1}) {
   if (0 <= i + ofs && i + ofs < discretization_points) {
                   values[pos] = coefs[ofs + 1];
                    col_idxs[pos] = i + ofs;
                    ++pos;
               }
          row_ptrs[i + 1] = pos;
Generates the RHS vector given f and the boundary conditions.
template <typename Closure>
void generate_rhs(int discretization_points, Closure f, double u0, double u1,
                      double *rhs)
     const auto h = 1.0 / (discretization_points + 1);
     for (int i = 0; i < discretization_points; ++i) {
  const auto xi = (i + 1) * h;</pre>
         rhs[i] = -f(xi) * h * h;
     rhs[0] += u0;
     rhs[discretization_points - 1] += u1;
Prints the solution u.
void print_solution(int discretization_points, double u0, double u1,
                        const double *u)
     std::cout « u0 « '\n';
     for (int i = 0; i < discretization_points; ++i) {</pre>
```

```
std::cout « u[i] « '\n';
}
std::cout « u1 « std::endl;
}
```

Computes the 1-norm of the error given the computed u and the correct solution function correct\_u.

```
template <typename Closure>
double calculate_error(int discretization_points, const double *u,
                       Closure correct_u)
    const auto h = 1.0 / (discretization_points + 1);
    auto error = 0.0;
    for (int i = 0; i < discretization_points; ++i) {</pre>
       using std::abs;
       const auto xi = (i + 1) * h;
       error += abs(u[i] - correct_u(xi)) / abs(correct_u(xi));
    return error;
void solve_system(const std::string &executor_string,
                  unsigned int discretization_points, int *row_ptrs,
                  int *col_idxs, double *values, double *rhs, double *u,
                  double accuracy)
{
Some shortcuts
```

```
using vec = gko::matrix::Dense<double>;
using mtx = gko::matrix::Csr<double, int>;
using cg = gko::solver::Cg<double>;
using bj = gko::preconditioner::Jacobi<double, int>;
using val_array = gko::Array<double>;
using idx_array = gko::Array<int>;
const auto &dp = discretization_points;
```

#### Figure out where to run the code

### executor where Ginkgo will perform the computation

```
const auto exec = exec_map.at(executor_string); // throws if not valid
```

#### executor where the application initialized the data

```
const auto app_exec = exec_map["omp"];
```

Tell Ginkgo to use the data in our application

Matrix: we have to set the executor of the matrix to the one where we want SpMVs to run (in this case exec). When creating array views, we have to specify the executor where the data is (in this case  $app\_exec$ ).

If the two do not match, Ginkgo will automatically create a copy of the data on exec (however, it will not copy the data back once it is done

here this is not important since we are not modifying the matrix).

Solution: we have to be careful here - if the executors are different, once we compute the solution the array will not be automatically copied back to the original memory locations. Fortunately, whenever  $\mathtt{apply}$  is called on a linear operator (e.g. matrix, solver) the arguments automatically get copied to the executor where the operator is, and copied back once the operation is completed. Thus, in this case, we can just define the solution on  $\mathtt{app\_exec}$ , and it will be automatically transferred to/from  $\mathtt{exec}$  if needed.

```
Generate solver

This example solves a 1D Poisson equation:
    u : [0, 1] -> R
    u'' = f
    u(0) = u0
    u(1) = u1
using a finite difference method on an equidistant grid with 'K' discretization
points ('K' can be controlled with a command line parameter). The discretization
is done via the second order Taylor polynomial:
u(x + h) = u(x) - u'(x)h + 1/2 u''(x)h^2 + O(h^3)
u(x - h) = u(x) + u'(x)h + 1/2 u''(x)h^2 + O(h^3)
-u(x - h) + 2u(x) + -u(x + h) = -f(x)h^2 + O(h^3)
For an equidistant grid with K "inner" discretization points x1, \ldots, xk, and
step size h = 1 / (K + 1), the formula produces a system of linear equations
 2u_{-1} - u_{-2} = -f_{-1} h^2 + u_0 
-u_{-(k-1)} + 2u_{-k} - u_{-(k+1)} = -f_{-k} h^2, 
-u_{-(k-1)} + 2u_{-k} = -f_{-k} h^2 + u_1 
                                             k = 2, ..., K - 1
which is then solved using \operatorname{Ginkgo's} implementation of the \operatorname{CG} method
preconditioned with block-Jacobi. It is also possible to specify on which
executor Ginkgo will solve the system via the command line.
The function 'f' is set to 'f(x) = 6x' (making the solution 'u(x) = x^3'), but
that can be changed in the 'main' function.
The intention of the example is to show how Ginkgo can be integrated into
existing software - the 'generate_stencil_matrix', 'generate_rhs', 'print_solution', 'compute_error' and 'main' function do not reference Ginkgo at
all (i.e. they could have been there before the application developer decided to
use Ginkgo, and the only part where Ginkgo is introduced is inside the
'solve_system' function.

# **Chapter 23**

# The twentyseven-pt-stencil-solver program

The 27-point stencil example..

This example depends on simple-solver, poisson-solver, nine-pt-stencil-solver, three-pt-stencil-solver.

## Introduction

This example solves a 3D Poisson equation:

[  $Omega = (0,1)^3 \end{main} \bega = [0,1]^3 \end{main} \bega = Omega_b \beckslash Omega u : Omega \rightarrow R \ u'' = f \in Omega \ u = u_D \in \partial Omega \]$ 

using a finite difference method on an equidistant grid with K discretization points (K can be controlled with a command line parameter). The discretization may be done by any order Taylor polynomial. For an equidistant grid with K "inner" discretization points ((x1,y1,z1), \ldots, (xk,y1,z1),(x1,y2,z1), \ldots, (xk,yk,z1), (x1,y1,z2), \ldots, (xk,yk,zk)), step size (h = 1 / (K + 1)) and a stencil (\in \mathbb{R}^{3} \times 3 \times 3), the formula produces a system of linear equations

 $(\sum_{a,b,c=-1}^1 \text{stencil}(a,b,c) * u_{(i+a,j+b,k+c)} = -f_k h^2)$ , on any inner node with a neighborhood of inner nodes

On any node, where neighbor is on the border, the neighbor is replaced with a (-stencil(a,b,c) \* u\_{i+a,j+b,k+c}) and added to the right hand side vector. For example a node with a neighborhood of only face nodes may look like this

 $[\sum_{a,b,c=-1}^{(1,1,0)} stencil(a,b,c) * u_{(i+a,j+b,k+c)} = -f_k h^2$ 

•  $\sum_{a,b=-1}^{(1,1)} \text{stencil}(a,b,1) * u_{(i+a,j+b,k+1)}$ 

which is then solved using Ginkgo's implementation of the CG method preconditioned with block-Jacobi. It is also possible to specify on which executor Ginkgo will solve the system via the command line. The function f is set to (f(x,y,z)=6x+6y+6z) (making the solution  $(u(x,y,z)=x^3+y^3+z^3)$ ), but that can be changed in the main function. Also the stencil values for the core, the faces, the edge and the corners can be changed when passing additional parameters.

The intention of this is to show how generation of stencil values and the right hand side vector changes when increasing the dimension.

### About the example

# The commented program

```
This example solves a 3D Poisson equation:
      \Omega = (0,1)^3
      \Omega_b = [0,1]^3
                               (with boundary)
      \partial\Omega = \Omega_b \backslash \Omega
     u:\Omega_b -> R
u" = f in \Omega
     u = u_D \text{ on } \beta
using a finite difference method on an equidistant grid with 'K' discretization
points ('K' can be controlled with a command line parameter). The discretization
may be done by any order Taylor polynomial.
For an equidistant grid with K "inner" discretization points (x1,y1,z1), ...
(xk,y1,z1), (x1,y2,z1), ..., (xk,yk,z1), (x1,y1,z2), ..., (xk,yk,zk), step size h = 1 / (K + 1) and a stencil i \ R^{3} x 3 x 3, the formula produces a system of
linear equations
\sum_{a,b,c=-1}^{a,b,c=-1}^{1} \operatorname{stencil}(a,b,c) * u_{(i+a,j+b,k+c)} = -f_k h^2, on any inner
node with a neighborhood of inner nodes
On any node, where neighbor is on the border, the neighbor is replaced with a '-stencil(a,b,c) * u_{i+a,j+b,k+c}' and added to the right hand side vector.
For example a node with a neighborhood of only face nodes may look like this \sum_{sum_{a,b,c}=-1}^{(1,1,0)} stencil(a,b,c) * u_{(i+a,j+b,k+c)} = -f_k h^2 -
\sum_{a,b=-1}^{(1,1)} stencil(a,b,1) * u_{(i+a,j+b,k+1)}
which is then solved using Ginkgo's implementation of the CG method
preconditioned with block-Jacobi. It is also possible to specify on which
executor Ginkgo will solve the system via the command line. The function 'f' is set to 'f(x,y,z) = 6x + 6y + 6z' (making the solution
^{3} 'u(x,y,z) = x^3 + y^3 + z^3), but that can be charged in the 'main' function. Also the stencil values for the core, the faces, the edge and the corners can be
changed when passing additional parameters.
The intention of this is to show how generation of stencil values and the right
#include <array>
#include <chrono>
#include <ginkgo/ginkgo.hpp>
#include <iostream>
#include <map>
#include <string>
#include <vector>
Can be changed by passing additional parameters when executing the program
constexpr double default_alpha = 38 / 6.0;
constexpr double default_beta = -4.0 / 6.0;
constexpr double default_gamma = -1.0 / 6.0; constexpr double default_delta = -1.0 / 24.0;
/ * Possible alternative values can be for example
 * default_alpha = 28.0;
* default_beta = -1.0;
 * default_gamma = -1.0;
 * default_delta = -1.0;
Creates a stencil matrix in CSR format for the given number of discretization points.

                                    if ((x + i) >= 0 \&\& (x + i) < dp \&\& (y + j) >= 0 \&\&
                                         (y + j) < dp && (z + k) >= 0 && (z + k) < dp) {
                                         values[pos] = coefs[offset];
                                         col_idxs[pos] = index + i + dp * (j + dp * k);
                                         ++pos;
```

}

```
}
    row_ptrs[index + 1] = pos;
}
}
```

Generates the RHS vector given f and the boundary conditions.

```
template <typename Closure, typename ClosureT>
void generate_rhs(int dp, Closure f, ClosureT u, double *rhs, double *coefs)
{
   const size_t dp_2 = dp * dp;
   const auto h = 1.0 / (dp + 1.0);
   for (size_t k = 0; k < dp; ++k) {
      const auto zi = (k + 1) * h;
      for (size_t j = 0; j < dp; ++j) {
      const auto yi = (j + 1) * h;
      for (size_t i = 0; i < dp; ++i) {
       const auto xi = (i + 1) * h;
       const auto xi = (i + 1) * h;
      const auto xi = (i + 1) * h;
      const auto xi = (i + 1) * h;
      const auto xi = (i + 1) * h;
      const auto index = i + dp * (j + dp * k);
      rhs[index] = -f(xi, yi, zi) * h * h;
   }
}</pre>
```

This is the iteration over the surface of left and right side of the cube x - ortho to left, right y - ortho to top, bottom z - ortho to front, back

To avoid double counting we have to check if our previous calculations included this case

Now every side has to be checked

}

```
}
            }
        }
    }
Prints the solution u.

Figure out where to run the code
const auto omp = gko::OmpExecutor::create();
std::map<std::string, std::shared_ptr<gko::Executor» exec_map{</pre>
     {"omp", omp},
{"cuda", gko::CudaExecutor::create(0, omp)},
     {"reference", gko::ReferenceExecutor::create()}};
executor where Ginkgo will perform the computation
const auto exec = exec_map at(executor_string); // throws if not valid
executor where the application initialized the data
const auto app_exec = exec_map["omp"];
```

Tell Ginkgo to use the data in our application

Matrix: we have to set the executor of the matrix to the one where we want SpMVs to run (in this case exec). When creating array views, we have to specify the executor where the data is (in this case  $app\_exec$ ).

If the two do not match, Ginkgo will automatically create a copy of the data on exec (however, it will not copy the data back once it is done

here this is not important since we are not modifying the matrix).

Solution: we have to be careful here - if the executors are different, once we compute the solution the array will not be automatically copied back to the original memory locations. Fortunately, whenever apply is called on a linear operator (e.g. matrix, solver) the arguments automatically get copied to the executor where the operator is, and copied back once the operation is completed. Thus, in this case, we can just define the solution on  $app\_exec$ , and it will be automatically transferred to/from exec if needed.

```
and it will be automatically transferred to/from exec if needed.
auto x = vec::create(app_exec, gko::dim<2>(dp_3, 1),
                       val_array::view(app_exec, dp_3, u), 1);
Generate solver

This example solves a 3D Poisson equation:
```

\*\*\*\*\*\*\*\*\*\*\*\*GINKGO LICENSE>\*\*\*\*\*\*\*\*\*\*\*\*\*\*\*\*\*

```
\Omega = (0,1)^3
        \Omega = [0,1]^3
                                           (with boundary)
       \partial\Omega = \Omega_b \backslash \Omega
       u:\Omega_b -> R
u" = f in \Omega
       u = u_D on \partial\Omega
using a finite difference method on an equidistant grid with 'K' discretization
points ('K' can be controlled with a command line parameter). The discretization
may be done by any order Taylor polynomial. For an equidistant grid with K "inner" discretization points (x1,y1,z1), ...,
(xk,y1,z1),(x1,y2,z1),\ldots,(xk,yk,z1),(x1,y1,z2),\ldots,(xk,yk,zk), step size h = 1 / (K + 1) and a stencil \in \R^{3 x 3 x 3}, the formula produces a system of
linear equations
node with a neighborhood of inner nodes
On any node, where neighbor is on the border, the neighbor is replaced with a
'-stencil(a,b,c) * u_{i+a,j+b,k+c}' and added to the right hand side vector.
For example a node with a neighborhood of only face nodes may look like this
\sum_{a,b,c=-1}^{(1,1,0)} stencil(a,b,c) * u_{(i+a,j+b,k+c)} = -f_k h^2 - f_k h^2 - f_k
\sum_{a,b=-1}^{(1,1)} stencil(a,b,1) * u_{(i+a,j+b,k+1)}
which is then solved using Ginkgo's implementation of the CG method
preconditioned with block-Jacobi. It is also possible to specify on which
executor Ginkgo will solve the system via the command line. The function 'f' is set to 'f(x,y,z) = 6x + 6y + 6z' (making the solution
 u(x,y,z) = x^3 + y^3 + z^3), but that can be changed in the 'main' function.
Also the stencil values for the core, the faces, the edge and the corners can be
changed when passing additional parameters.
The intention of this is to show how generation of stencil values and the right
hand side vector changes when increasing the dimension.

# **Chapter 24**

# **Module Documentation**

# 24.1 CUDA Executor

A module dedicated to the implementation and usage of the CUDA executor in Ginkgo.

## Classes

• class gko::CudaExecutor

This is the Executor subclass which represents the CUDA device.

# 24.1.1 Detailed Description

A module dedicated to the implementation and usage of the CUDA executor in Ginkgo.

### 24.2 Executors

A module dedicated to the implementation and usage of the executors in Ginkgo.

## **Modules**

CUDA Executor

A module dedicated to the implementation and usage of the CUDA executor in Ginkgo.

OpenMP Executor

A module dedicated to the implementation and usage of the OpenMP executor in Ginkgo.

Reference Executor

A module dedicated to the implementation and usage of the Reference executor in Ginkgo.

#### **Classes**

· class gko::Operation

Operations can be used to define functionalities whose implementations differ among devices.

· class gko::Executor

The first step in using the Ginkgo library consists of creating an executor.

class gko::executor\_deleter< T >

This is a deleter that uses an executor's free method to deallocate the data.

· class gko::OmpExecutor

This is the Executor subclass which represents the OpenMP device (typically CPU).

· class gko::ReferenceExecutor

This is a specialization of the OmpExecutor, which runs the reference implementations of the kernels used for debugging purposes.

· class gko::CudaExecutor

This is the Executor subclass which represents the CUDA device.

#### **Macros**

#define GKO\_REGISTER\_OPERATION(\_name, \_kernel)

Binds a set of device-specific kernels to an Operation.

### 24.2.1 Detailed Description

A module dedicated to the implementation and usage of the executors in Ginkgo.

Below, we provide a brief introduction to executors in Ginkgo, how they have been implemented, how to best make use of them and how to add new executors.

24.2 Executors 147

## 24.2.2 Executors in Ginkgo.

The first step in using the Ginkgo library consists of creating an executor. Executors are used to specify the location for the data of linear algebra objects, and to determine where the operations will be executed. Ginkgo currently supports three different executor types:

- OpenMP Executor specifies that the data should be stored and the associated operations executed on an OpenMP-supporting device (e.g. host CPU);
- CUDA Executor specifies that the data should be stored and the operations executed on the NVIDIA GPU accelerator;
- Reference Executor executes a non-optimized reference implementation, which can be used to debug the library.

### 24.2.3 Macro Definition Documentation

### 24.2.3.1 GKO REGISTER OPERATION

Binds a set of device-specific kernels to an Operation.

It also defines a helper function which creates the associated operation. Any input arguments passed to the helper function are forwarded to the kernel when the operation is executed.

The kernels used to bind the operation are searched in kernels::DEV\_TYPE namespace, where DEV\_TYPE is replaced by omp, cuda and reference.

### **Parameters**

_name	operation name
_kernel	kernel which will be bound to the operation

### 24.2.3.2 Example

```
// reference code
}
}
// Bind the kernels to the operation
GKO_REGISTER_OPERATION(my_op, my_kernel);
int main() {
    // create executors
    auto omp = OmpExecutor::create();
    auto cuda = CudaExecutor::create(omp, 0);
    auto ref = ReferenceExecutor::create();
    // create the operation
    auto op = make_my_op(5); // x = 5
    omp->run(op); // run omp kernel
    cuda->run(op); // run cuda kernel
    ref->run(op); // run reference kernel
}
```

24.3 Factorizations 149

# 24.3 Factorizations

A module dedicated to the implementation and usage of the Factorizations in Ginkgo.

# **Namespaces**

• gko::factorization

The Factorization namespace.

### **Classes**

• class gko::factorization::Parllu< ValueType, IndexType > ParlLU is an incomplete LU factorization which is computed in parallel.

# 24.3.1 Detailed Description

A module dedicated to the implementation and usage of the Factorizations in Ginkgo.

# 24.4 Linear Operators

A module dedicated to the implementation and usage of the Linear operators in Ginkgo.

### **Modules**

Factorizations

A module dedicated to the implementation and usage of the Factorizations in Ginkgo.

· SpMV employing different Matrix formats

A module dedicated to the implementation and usage of the various Matrix Formats in Ginkgo.

Preconditioners

A module dedicated to the implementation and usage of the Preconditioners in Ginkgo.

Solvers

A module dedicated to the implementation and usage of the Solvers in Ginkgo.

#### **Classes**

class gko::Combination < ValueType >

The Combination class can be used to construct a linear combination of multiple linear operators  $c1 * op1 + c2 * op2 + \dots$ 

class gko::Composition < ValueType >

The Composition class can be used to compose linear operators op1, op2, ..., opn and obtain the operator op1 \* op2 \* ...

class gko::LinOpFactory

A LinOpFactory represents a higher order mapping which transforms one linear operator into another.

class gko::ReadableFromMatrixData< ValueType, IndexType >

A LinOp implementing this interface can read its data from a matrix\_data structure.

class gko::WritableToMatrixData< ValueType, IndexType >

A LinOp implementing this interface can write its data to a matrix\_data structure.

· class gko::Preconditionable

A LinOp implementing this interface can be preconditioned.

class gko::EnableLinOp
 ConcreteLinOp
 PolymorphicBase

The EnableLinOp mixin can be used to provide sensible default implementations of the majority of the LinOp and PolymorphicObject interface.

class gko::Perturbation < ValueType >

The Perturbation class can be used to construct a LinOp to represent the operation (identity + scalar \* basis \* projector).

class gko::matrix::Coo< ValueType, IndexType >

COO stores a matrix in the coordinate matrix format.

class gko::matrix::Csr< ValueType, IndexType >

CSR is a matrix format which stores only the nonzero coefficients by compressing each row of the matrix (compressed sparse row format).

class gko::matrix::Dense< ValueType >

Dense is a matrix format which explicitly stores all values of the matrix.

class gko::matrix::Ell< ValueType, IndexType >

ELL is a matrix format where stride with explicit zeros is used such that all rows have the same number of stored elements.

class gko::matrix::Hybrid< ValueType, IndexType >

HYBRID is a matrix format which splits the matrix into ELLPACK and COO format.

class gko::matrix::Identity< ValueType >

24.4 Linear Operators 151

This class is a utility which efficiently implements the identity matrix (a linear operator which maps each vector to itself).

class gko::matrix::IdentityFactory
 ValueType >

This factory is a utility which can be used to generate Identity operators.

class gko::matrix::Sellp< ValueType, IndexType >

SELL-P is a matrix format similar to ELL format.

class gko::matrix::SparsityCsr< ValueType, IndexType >

SparsityCsr is a matrix format which stores only the sparsity pattern of a sparse matrix by compressing each row of the matrix (compressed sparse row format).

class gko::preconditioner::llu< LSolverType, USolverType, ReverseApply, IndexTypeParllu >

The Incomplete LU (ILU) preconditioner solves the equation LUx = b for a given lower triangular matrix L, an upper triangular matrix U and the right hand side b (can contain multiple right hand sides).

struct gko::preconditioner::block\_interleaved\_storage\_scheme < IndexType >

Defines the parameters of the interleaved block storage scheme used by block-Jacobi blocks.

class gko::preconditioner::Jacobi < ValueType, IndexType >

A block-Jacobi preconditioner is a block-diagonal linear operator, obtained by inverting the diagonal blocks of the source operator.

class gko::solver::Bicgstab
 ValueType >

BiCGSTAB or the Bi-Conjugate Gradient-Stabilized is a Krylov subspace solver.

class gko::solver::Cg< ValueType >

CG or the conjugate gradient method is an iterative type Krylov subspace method which is suitable for symmetric positive definite methods.

class gko::solver::Cgs< ValueType >

CGS or the conjugate gradient square method is an iterative type Krylov subspace method which is suitable for general systems.

class gko::solver::Fcg< ValueType >

FCG or the flexible conjugate gradient method is an iterative type Krylov subspace method which is suitable for symmetric positive definite methods.

class gko::solver::Gmres < ValueType >

GMRES or the generalized minimal residual method is an iterative type Krylov subspace method which is suitable for nonsymmetric linear systems.

class gko::solver::LowerTrs< ValueType, IndexType >

LowerTrs is the triangular solver which solves the system L x = b, when L is a lower triangular matrix.

class gko::solver::UpperTrs< ValueType, IndexType >

UpperTrs is the triangular solver which solves the system Ux = b, when U is an upper triangular matrix.

### **Macros**

• #define GKO\_CREATE\_FACTORY\_PARAMETERS(\_parameters\_name, \_factory\_name)

This Macro will generate a new type containing the parameters for the factory\_factory\_name.

• #define GKO\_ENABLE\_LIN\_OP\_FACTORY(\_lin\_op, \_parameters\_name, \_factory\_name)

This macro will generate a default implementation of a LinOpFactory for the LinOp subclass it is defined in.

#define GKO\_ENABLE\_BUILD\_METHOD(\_factory\_name)

Defines a build method for the factory, simplifying its construction by removing the repetitive typing of factory's name.

• #define GKO\_FACTORY\_PARAMETER(\_name, ...)

Creates a factory parameter in the factory parameters structure.

### **Typedefs**

template<typename ConcreteFactory , typename ConcreteLinOp , typename ParametersType , typename PolymorphicBase = Lin←</li>
 OpFactory>

using gko::EnableDefaultLinOpFactory = EnableDefaultFactory< ConcreteFactory, ConcreteLinOp, ParametersType, PolymorphicBase >

This is an alias for the EnableDefaultFactory mixin, which correctly sets the template parameters to enable a subclass of LinOpFactory.

## 24.4.1 Detailed Description

A module dedicated to the implementation and usage of the Linear operators in Ginkgo.

Below we elaborate on one of the most important concepts of Ginkgo, the linear operator. The linear operator (LinOp) is a base class for all linear algebra objects in Ginkgo. The main benefit of having a single base class for the entire collection of linear algebra objects (as opposed to having separate hierarchies for matrices, solvers and preconditioners) is the generality it provides.

## 24.4.2 Advantages of this approach and usage

A common interface often allows for writing more generic code. If a user's routine requires only operations provided by the LinOp interface, the same code can be used for any kind of linear operators, independent of whether these are matrices, solvers or preconditioners. This feature is also extensively used in Ginkgo itself. For example, a preconditioner used inside a Krylov solver is a LinOp. This allows the user to supply a wide variety of preconditioners: either the ones which were designed to be used in this scenario (like ILU or block-Jacobi), a user-supplied matrix which is known to be a good preconditioner for the specific problem, or even another solver (e.g., if constructing a flexible GMRES solver).

For example, a matrix free implementation would require the user to provide an apply implementation and instead of passing the generated matrix to the solver, they would have to provide their apply implementation for all the executors needed and no other code needs to be changed. See The custom-matrix-format program example for more details.

### 24.4.3 Linear operator as a concept

The linear operator (LinOp) is a base class for all linear algebra objects in Ginkgo. The main benefit of having a single base class for the entire collection of linear algebra objects (as opposed to having separate hierarchies for matrices, solvers and preconditioners) is the generality it provides.

First, since all subclasses provide a common interface, the library users are exposed to a smaller set of routines. For example, a matrix-vector product, a preconditioner application, or even a system solve are just different terms given to the operation of applying a certain linear operator to a vector. As such, Ginkgo uses the same routine name, LinOp::apply() for each of these operations, where the actual operation performed depends on the type of linear operator involved in the operation.

Second, a common interface often allows for writing more generic code. If a user's routine requires only operations provided by the LinOp interface, the same code can be used for any kind of linear operators, independent of whether these are matrices, solvers or preconditioners. This feature is also extensively used in Ginkgo itself. For example, a preconditioner used inside a Krylov solver is a LinOp. This allows the user to supply a wide variety of preconditioners: either the ones which were designed to be used in this scenario (like ILU or block-Jacobi), a user-supplied matrix which is known to be a good preconditioner for the specific problem, or even another solver (e.g., if constructing a flexible GMRES solver).

A key observation for providing a unified interface for matrices, solvers, and preconditioners is that the most common operation performed on all of them can be expressed as an application of a linear operator to a vector:

- the sparse matrix-vector product with a matrix A is a linear operator application y = Ax;
- the application of a preconditioner is a linear operator application  $y = M^{-1}x$ , where M is an approximation of the original system matrix A (thus a preconditioner represents an "approximate inverse" operator  $M^{-1}$ ).
- the system solve Ax = b can be viewed as linear operator application  $x = A^{-1}b$  (it goes without saying that the implementation of linear system solves does not follow this conceptual idea), so a linear system solver can be viewed as a representation of the operator  $A^{-1}$ .

24.4 Linear Operators 153

Finally, direct manipulation of LinOp objects is rarely required in simple scenarios. As an illustrative example, one could construct a fixed-point iteration routine  $x_{k+1} = Lx_k + b$  as follows:

```
std::unique_ptr<matrix::Dense<> calculate_fixed_point(
    int iters, const LinOp *L, const matrix::Dense<> *x0
    const matrix::Dense<> *b)
{
    auto x = gko::clone(x0);
    auto tmp = gko::clone(x0);
    auto one = Dense<>::create(L->get_executor(), {1.0,});
    for (int i = 0; i < iters; ++i) {
        L->apply(gko::lend(tmp), gko::lend(x));
        x->add_scaled(gko::lend(one), gko::lend(b));
        tmp->copy_from(gko::lend(x));
    }
    return x;
}
```

Here, if L is a matrix, LinOp::apply() refers to the matrix vector product, and L->apply(a, b) computes  $b = L \cdot a$ . x->add\_scaled(one.get(), b.get()) is the axpy vector update x := x + b.

The interesting part of this example is the apply() routine at line 4 of the function body. Since this routine is part of the LinOp base class, the fixed-point iteration routine can calculate a fixed point not only for matrices, but for any type of linear operator.

**Linear Operators** 

### 24.4.4 Macro Definition Documentation

### 24.4.4.1 GKO\_CREATE\_FACTORY\_PARAMETERS

This Macro will generate a new type containing the parameters for the factory \_factory\_name.

For more details, see GKO\_ENABLE\_LIN\_OP\_FACTORY(). It is required to use this macro before calling the macro GKO\_ENABLE\_LIN\_OP\_FACTORY(). It is also required to use the same names for all parameters between both macros.

### Parameters

_parameters_name	name of the parameters member in the class
_factory_name	name of the generated factory type

#### 24.4.4.2 GKO ENABLE BUILD METHOD

```
#define GKO_ENABLE_BUILD_METHOD(
```

```
_factory_name )
```

#### Value:

```
static auto build()->decltype(_factory_name::create())
{
    return _factory_name::create();
}
static_assert(true,
    "This assert is used to counter the false positive extra " \
    "semi-colon warnings")
```

Defines a build method for the factory, simplifying its construction by removing the repetitive typing of factory's name.

#### **Parameters**

\_\_factory\_\_name | the factory for which to define the method

### 24.4.4.3 GKO ENABLE LIN OP FACTORY

This macro will generate a default implementation of a LinOpFactory for the LinOp subclass it is defined in.

It is required to first call the macro GKO\_CREATE\_FACTORY\_PARAMETERS() before this one in order to instantiate the parameters type first.

The list of parameters for the factory should be defined in a code block after the macro definition, and should contain a list of GKO\_FACTORY\_PARAMETER declarations. The class should provide a constructor with signature \_lin← \_op(const \_factory\_name \*, std::shared\_ptr<const LinOp>) which the factory will use a callback to construct the object.

A minimal example of a linear operator is the following:

### MyLinOp can then be created as follows:

```
auto exec = gko::ReferenceExecutor::create();

// create a factory with default 'my_value' parameter
auto fact = MyLinOp::build().on(exec);

// create a operator using the factory:
auto my_op = fact->generate(gko::matrix::Identity::create(exec, 2));
std::cout « my_op->get_my_parameters().my_value; // prints 5

// create a factory with custom 'my_value' parameter
auto fact = MyLinOp::build().with_my_value(0).on(exec);

// create a operator using the factory:
auto my_op = fact->generate(gko::matrix::Identity::create(exec, 2));
std::cout « my_op->get_my_parameters().my_value; // prints 0
```

24.4 Linear Operators 155

#### Note

It is possible to combine both the #GKO\_CREATE\_FACTORY\_PARAMETER() macro with this one in a unique macro for class **templates** (not with regular classes). Splitting this into two distinct macros allows to use them in all contexts. See  $\frac{\text{https://stackoverflow.com/q/50202718/9385966}}{\text{https://stackoverflow.com/q/50202718/9385966}}$  for more details.

### **Parameters**

_lin_op	concrete operator for which the factory is to be created [CRTP parameter]
_parameters_name	name of the parameters member in the class (its type is
	<pre>&lt;_parameters_name&gt;_type, the protected member's name is</pre>
	<_parameters_name>_, and the public getter's name is
	<pre>get_&lt;_parameters_name&gt;())</pre>
_factory_name	name of the generated factory type

### 24.4.4.4 GKO\_FACTORY\_PARAMETER

Creates a factory parameter in the factory parameters structure.

#### **Parameters**

_name	name of the parameter
<strong>VA_ARGS</strong>	default value of the parameter

### See also

GKO\_ENABLE\_LIN\_OP\_FACTORY for more details, and usage example

# 24.4.5 Typedef Documentation

# 24.4.5.1 EnableDefaultLinOpFactory

template<typename ConcreteFactory , typename ConcreteLinOp , typename ParametersType , typename PolymorphicBase = LinOpFactory> using gko::EnableDefaultLinOpFactory = typedef EnableDefaultFactory<ConcreteFactory, Concrete← LinOp, ParametersType, PolymorphicBase>

This is an alias for the EnableDefaultFactory mixin, which correctly sets the template parameters to enable a subclass of LinOpFactory.

### **Template Parameters**

ConcreteFactory	the concrete factory which is being implemented [CRTP parmeter]
ConcreteLinOp	the concrete LinOp type which this factory produces, needs to have a constructor which takes a const ConcreteFactory *, and an std::shared_ptr <const linop=""> as parameters.</const>
ParametersType	a subclass of enable_parameters_type template which defines all of the parameters of the factory
PolymorphicBase	parent of ConcreteFactory in the polymorphic hierarchy, has to be a subclass of LinOpFactory

24.5 Logging 157

# 24.5 Logging

A module dedicated to the implementation and usage of the Logging in Ginkgo.

## **Namespaces**

• gko::log

The logger namespace.

### **Classes**

class gko::log::Convergence < ValueType >
 Convergence is a Logger which logs data strictly from the criterion\_check\_completed event.

class gko::log::Stream
 ValueType >

Stream is a Logger which logs every event to a stream.

## 24.5.1 Detailed Description

A module dedicated to the implementation and usage of the Logging in Ginkgo.

The Logger class represents a simple Logger object. It comprises all masks and events internally. Every new logging event addition should be done here. The Logger class also provides a default implementation for most events which do nothing, therefore it is not an obligation to change all classes which derive from Logger, although it is good practice. The logger class is built using event masks to control which events should be logged, and which should not.

# 24.6 SpMV employing different Matrix formats

A module dedicated to the implementation and usage of the various Matrix Formats in Ginkgo.

### **Classes**

class gko::matrix::Coo< ValueType, IndexType >

COO stores a matrix in the coordinate matrix format.

class gko::matrix::Csr< ValueType, IndexType >

CSR is a matrix format which stores only the nonzero coefficients by compressing each row of the matrix (compressed sparse row format).

class gko::matrix::Dense
 ValueType >

Dense is a matrix format which explicitly stores all values of the matrix.

class gko::matrix::Ell< ValueType, IndexType >

ELL is a matrix format where stride with explicit zeros is used such that all rows have the same number of stored elements.

class gko::matrix::Hybrid< ValueType, IndexType >

HYBRID is a matrix format which splits the matrix into ELLPACK and COO format.

class gko::matrix::Identity< ValueType >

This class is a utility which efficiently implements the identity matrix (a linear operator which maps each vector to itself).

class gko::matrix::IdentityFactory
 ValueType >

This factory is a utility which can be used to generate Identity operators.

class gko::matrix::Sellp< ValueType, IndexType >

SELL-P is a matrix format similar to ELL format.

class gko::matrix::SparsityCsr< ValueType, IndexType >

SparsityCsr is a matrix format which stores only the sparsity pattern of a sparse matrix by compressing each row of the matrix (compressed sparse row format).

### **Functions**

template<typename Matrix , typename... TArgs>
 std::unique\_ptr< Matrix > gko::initialize (size\_type stride, std::initializer\_list< typename Matrix::value\_type
 > vals, std::shared ptr< const Executor > exec, TArgs &&... create args)

Creates and initializes a column-vector.

template<typename Matrix , typename... TArgs>
 std::unique\_ptr< Matrix > gko::initialize (std::initializer\_list< typename Matrix::value\_type > vals, std
 ::shared\_ptr< const Executor > exec, TArgs &&... create\_args)

Creates and initializes a column-vector.

template<typename Matrix , typename... TArgs>
 std::unique\_ptr< Matrix > gko::initialize (size\_type stride, std::initializer\_list< std::initializer\_list< typename
 Matrix::value\_type >> vals, std::shared\_ptr< const Executor > exec, TArgs &&... create\_args)

Creates and initializes a matrix.

template<typename Matrix , typename... TArgs>
 std::unique\_ptr< Matrix > gko::initialize (std::initializer\_list< std::initializer\_list< typename Matrix::value\_
 type >> vals, std::shared\_ptr< const Executor > exec, TArgs &&... create\_args)

Creates and initializes a matrix.

# 24.6.1 Detailed Description

A module dedicated to the implementation and usage of the various Matrix Formats in Ginkgo.

#### 24.6.2 Function Documentation

#### 24.6.2.1 initialize() [1/4]

Creates and initializes a matrix.

This function first creates a temporary Dense matrix, fills it with passed in values, and then converts the matrix to the requested type.

#### **Template Parameters**

Matrix	matrix type to initialize (Dense has to implement the ConvertibleTo <matrix> interface)</matrix>
TArgs	argument types for Matrix::create method (not including the implied Executor as the first argument)

#### **Parameters**

stride	row stride for the temporary Dense matrix
vals	values used to initialize the matrix
exec	Executor associated to the matrix
create_args	additional arguments passed to Matrix::create, not including the Executor, which is passed as the first argument

```
606
        using dense = matrix::Dense<typename Matrix::value_type>;
        size_type num_rows = vals.size();
size_type num_cols = num_rows > 0 ? begin(vals)->size() : 1;
607
608
609
        auto tmp =
610
            dense::create(exec->get_master(), dim<2>{num_rows, num_cols}, stride);
611
        size_type ridx = 0;
612
        for (const auto &row : vals) {
            size_type cidx = 0;
for (const auto &elem : row) {
613
614
                tmp->at(ridx, cidx) = elem;
615
616
                 ++cidx;
618
             ++ridx;
619
        auto mtx = Matrix::create(exec, std::forward<TArgs>(create_args)...);
62.0
        tmp->move_to(mtx.get());
621
622
        return mtx;
```

References gko::matrix::Dense< ValueType >::at().

## 24.6.2.2 initialize() [2/4]

```
template<typename Matrix , typename... TArgs>
std::unique_ptr<Matrix> gko::initialize (
```

160 Module Documentation

```
size_type stride,
std::initializer_list< typename Matrix::value_type > vals,
std::shared_ptr< const Executor > exec,
TArgs &&... create_args )
```

Creates and initializes a column-vector.

This function first creates a temporary Dense matrix, fills it with passed in values, and then converts the matrix to the requested type.

#### **Template Parameters**

Matrix   matrix type to initialize (Dense has to implement the ConvertibleTo <matrix> interface)</matrix>		
	TArgs	argument types for Matrix::create method (not including the implied Executor as the first argument)

#### **Parameters**

stride	row stride for the temporary Dense matrix
vals	values used to initialize the vector
exec	Executor associated to the vector
create_args	additional arguments passed to Matrix::create, not including the Executor, which is passed as the first argument

References gko::matrix::Dense< ValueType >::at().

#### 24.6.2.3 initialize() [3/4]

Creates and initializes a matrix.

This function first creates a temporary Dense matrix, fills it with passed in values, and then converts the matrix to the requested type. The stride of the intermediate Dense matrix is set to the number of columns of the initializer list.

# **Template Parameters**

Matrix	matrix type to initialize (Dense has to implement the ConvertibleTo <matrix> interface)</matrix>
TArgs	argument types for Matrix::create method (not including the implied Executor as the first argument)

#### **Parameters**

vals	values used to initialize the matrix	
exec	Executor associated to the matrix	
create_args	additional arguments passed to Matrix::create, not including the Executor, which is passed as the first argument	

# 24.6.2.4 initialize() [4/4]

Creates and initializes a column-vector.

This function first creates a temporary Dense matrix, fills it with passed in values, and then converts the matrix to the requested type. The stride of the intermediate Dense matrix is set to 1.

# **Template Parameters**

Matrix	matrix type to initialize (Dense has to implement the ConvertibleTo <matrix> interface)</matrix>
TArgs	argument types for Matrix::create method (not including the implied Executor as the first argument)

#### **Parameters**

vals	values used to initialize the vector	
exec	Executor associated to the vector	
create_args	additional arguments passed to Matrix::create, not including the Executor, which is passed as the first argument	

162 Module Documentation

# 24.7 OpenMP Executor

A module dedicated to the implementation and usage of the OpenMP executor in Ginkgo.

# **Classes**

• class gko::OmpExecutor

This is the Executor subclass which represents the OpenMP device (typically CPU).

# 24.7.1 Detailed Description

A module dedicated to the implementation and usage of the OpenMP executor in Ginkgo.

24.8 Preconditioners 163

# 24.8 Preconditioners

A module dedicated to the implementation and usage of the Preconditioners in Ginkgo.

# **Namespaces**

• gko::preconditioner

The Preconditioner namespace.

#### Classes

· class gko::Preconditionable

A LinOp implementing this interface can be preconditioned.

• class gko::preconditioner::llu< LSolverType, USolverType, ReverseApply, IndexTypeParllu >

The Incomplete LU (ILU) preconditioner solves the equation LUx = b for a given lower triangular matrix L, an upper triangular matrix U and the right hand side b (can contain multiple right hand sides).

struct gko::preconditioner::block\_interleaved\_storage\_scheme < IndexType >

Defines the parameters of the interleaved block storage scheme used by block-Jacobi blocks.

class gko::preconditioner::Jacobi< ValueType, IndexType >

A block-Jacobi preconditioner is a block-diagonal linear operator, obtained by inverting the diagonal blocks of the source operator.

# 24.8.1 Detailed Description

A module dedicated to the implementation and usage of the Preconditioners in Ginkgo.

164 Module Documentation

# 24.9 Reference Executor

A module dedicated to the implementation and usage of the Reference executor in Ginkgo.

# **Classes**

• class gko::ReferenceExecutor

This is a specialization of the OmpExecutor, which runs the reference implementations of the kernels used for debugging purposes.

# 24.9.1 Detailed Description

A module dedicated to the implementation and usage of the Reference executor in Ginkgo.

24.10 Solvers 165

## 24.10 Solvers

A module dedicated to the implementation and usage of the Solvers in Ginkgo.

# **Namespaces**

· gko::solver

The ginkgo Solve namespace.

#### Classes

class gko::solver::Bicgstab
 ValueType >

BiCGSTAB or the Bi-Conjugate Gradient-Stabilized is a Krylov subspace solver.

class gko::solver::Cg< ValueType >

CG or the conjugate gradient method is an iterative type Krylov subspace method which is suitable for symmetric positive definite methods.

class gko::solver::Cgs< ValueType >

CGS or the conjugate gradient square method is an iterative type Krylov subspace method which is suitable for general systems.

class gko::solver::Fcg< ValueType >

FCG or the flexible conjugate gradient method is an iterative type Krylov subspace method which is suitable for symmetric positive definite methods.

class gko::solver::Gmres < ValueType >

GMRES or the generalized minimal residual method is an iterative type Krylov subspace method which is suitable for nonsymmetric linear systems.

class gko::solver::LowerTrs< ValueType, IndexType >

LowerTrs is the triangular solver which solves the system L x = b, when L is a lower triangular matrix.

class gko::solver::UpperTrs< ValueType, IndexType >

UpperTrs is the triangular solver which solves the system Ux = b, when U is an upper triangular matrix.

# 24.10.1 Detailed Description

A module dedicated to the implementation and usage of the Solvers in Ginkgo.

166 Module Documentation

# 24.11 Stopping criteria

A module dedicated to the implementation and usage of the Stopping Criteria in Ginkgo.

## **Namespaces**

• gko::stop

The Stopping criterion namespace.

#### Classes

· class gko::stop::Combined

The Combined class is used to combine multiple criterions together through an OR operation.

class gko::stop::Iteration

The Iteration class is a stopping criterion which stops the iteration process after a preset number of iterations.

class gko::stop::ResidualNormReduction< ValueType >

The ResidualNormReduction class is a stopping criterion which stops the iteration process when the relative residual norm is below a certain threshold.

· class gko::stopping status

This class is used to keep track of the stopping status of one vector.

class gko::stop::Time

The Time class is a stopping criterion which stops the iteration process after a certain amout of time has passed.

#### **Macros**

#define GKO\_ENABLE\_CRITERION\_FACTORY(\_criterion, \_parameters\_name, \_factory\_name)
 This macro will generate a default implementation of a CriterionFactory for the Criterion subclass it is defined in.

## **Functions**

template < typename Factory Container >
 std::shared\_ptr < const Criterion Factory > gko::stop::combine (Factory Container & factories)
 Combines multiple criterion factories into a single combined criterion factory.

## 24.11.1 Detailed Description

A module dedicated to the implementation and usage of the Stopping Criteria in Ginkgo.

## 24.11.2 Macro Definition Documentation

#### 24.11.2.1 GKO\_ENABLE\_CRITERION\_FACTORY

This macro will generate a default implementation of a CriterionFactory for the Criterion subclass it is defined in.

This macro is very similar to the macro #ENABLE\_LIN\_OP\_FACTORY(). A more detailed description of the use of these type of macros can be found there.

24.11 Stopping criteria 167

#### **Parameters**

_criterion	concrete operator for which the factory is to be created [CRTP parameter]
_parameters_name	name of the parameters member in the class (its type is
	<pre>&lt;_parameters_name&gt;_type, the protected member's name is</pre>
	<pre>&lt;_parameters_name&gt;_, and the public getter's name is</pre>
	<pre>get_&lt;_parameters_name&gt;())</pre>
_factory_name	name of the generated factory type

## 24.11.3 Function Documentation

## 24.11.3.1 combine()

Combines multiple criterion factories into a single combined criterion factory.

This function treats a singleton container as a special case and avoids creating an additional object and just returns the input factory.

#### **Template Parameters**

FactoryContainer	a random access container type
------------------	--------------------------------

#### **Parameters**

	factories	a list of factories to combined
--	-----------	---------------------------------

## Returns

a combined criterion factory if the input contains multiple factories or the input factory if the input contains only one factory

```
117 {
118
        switch (factories.size()) {
119
120
            GKO_NOT_SUPPORTED(nullptr);
121
            return nullptr;
122
        case 1:
123
           return factories[0];
124
        default:
           auto exec = factories[0]->get_executor();
125
126
127
            return Combined::build()
                .with_criteria(std::forward<FactoryContainer>(factories))
128
                .on(exec);
        }
130 }
```

168 Module Documentation

# **Chapter 25**

# **Namespace Documentation**

# 25.1 gko Namespace Reference

The Ginkgo namespace.

# **Namespaces**

accessor

The accessor namespace.

· factorization

The Factorization namespace.

• log

The logger namespace.

matrix

The matrix namespace.

name\_demangling

The name demangling namespace.

· preconditioner

The Preconditioner namespace.

solver

The ginkgo Solve namespace.

• stop

The Stopping criterion namespace.

• syn

The Synthesizer namespace.

xstd

The namespace for functionalities after C++11 standard.

#### **Classes**

class AbstractFactory

The AbstractFactory is a generic interface template that enables easy implementation of the abstract factory design pattern.

class AllocationError

AllocationError is thrown if a memory allocation fails.

class Array

An Array is a container which encapsulates fixed-sized arrays, stored on the Executor tied to the Array.

class BadDimension

BadDimension is thrown if an operation is being applied to a LinOp with bad dimensions.

· class Combination

The Combination class can be used to construct a linear combination of multiple linear operators  $c1 * op1 + c2 * op2 + \dots$ 

· class Composition

The Composition class can be used to compose linear operators op1, op2, ..., opn and obtain the operator op1\*op2\*...

class ConvertibleTo

Convertible To interface is used to mark that the implementer can be converted to the object of ResultType.

class copy back deleter

A copy\_back\_deleter is a type of deleter that copies the data to an internally referenced object before performing the deletion.

class CublasError

CublasError is thrown when a cuBLAS routine throws a non-zero error code.

class CudaError

CudaError is thrown when a CUDA routine throws a non-zero error code.

class CudaExecutor

This is the Executor subclass which represents the CUDA device.

· class CusparseError

CusparseError is thrown when a cuSPARSE routine throws a non-zero error code.

· struct default\_converter

Used to convert objects of type S to objects of type R using static\_cast.

struct dim

A type representing the dimensions of a multidimensional object.

· class DimensionMismatch

DimensionMismatch is thrown if an operation is being applied to LinOps of incompatible size.

struct enable\_parameters\_type

The enable\_parameters\_type mixin is used to create a base implementation of the factory parameters structure.

class EnableAbstractPolymorphicObject

This mixin inherits from (a subclass of) PolymorphicObject and provides a base implementation of a new abstract object.

class EnableCreateMethod

This mixin implements a static create() method on ConcreteType that dynamically allocates the memory, uses the passed-in arguments to construct the object, and returns an std::unique\_ptr to such an object.

class EnableDefaultFactory

This mixin provides a default implementation of a concrete factory.

class EnableLinOp

The EnableLinOp mixin can be used to provide sensible default implementations of the majority of the LinOp and PolymorphicObject interface.

· class EnablePolymorphicAssignment

This mixin is used to enable a default PolymorphicObject::copy\_from() implementation for objects that have implemented conversions between them.

· class EnablePolymorphicObject

This mixin inherits from (a subclass of) PolymorphicObject and provides a base implementation of a new concrete polymorphic object.

· class Error

The Error class is used to report exceptional behaviour in library functions.

class Executor

The first step in using the Ginkgo library consists of creating an executor.

· class executor deleter

This is a deleter that uses an executor's free method to deallocate the data.

class KernelNotFound

KernelNotFound is thrown if Ginkgo cannot find a kernel which satisfies the criteria imposed by the input arguments.

class LinOpFactory

A LinOpFactory represents a higher order mapping which transforms one linear operator into another.

· struct matrix data

This structure is used as an intermediate data type to store a sparse matrix.

class NotCompiled

NotCompiled is thrown when attempting to call an operation which is a part of a module that was not compiled on the system.

class NotImplemented

NotImplemented is thrown in case an operation has not yet been implemented (but will be implemented in the future).

class NotSupported

NotSupported is thrown in case it is not possible to perform the requested operation on the given object type.

· class null deleter

This is a deleter that does not delete the object.

class OmpExecutor

This is the Executor subclass which represents the OpenMP device (typically CPU).

class Operation

Operations can be used to define functionalities whose implementations differ among devices.

class OutOfBoundsError

OutOfBoundsError is thrown if a memory access is detected to be out-of-bounds.

class Perturbation

The Perturbation class can be used to construct a LinOp to represent the operation (identity + scalar \* basis \* projector).

class PolymorphicObject

A PolymorphicObject is the abstract base for all "heavy" objects in Ginkgo that behave polymorphically.

· class precision\_reduction

This class is used to encode storage precisions of low precision algorithms.

class Preconditionable

A LinOp implementing this interface can be preconditioned.

class range

A range is a multidimensional view of the memory.

class ReadableFromMatrixData

A LinOp implementing this interface can read its data from a matrix\_data structure.

· class ReferenceExecutor

This is a specialization of the OmpExecutor, which runs the reference implementations of the kernels used for debugging purposes.

struct span

A span is a lightweight structure used to create sub-ranges from other ranges.

class stopping\_status

This class is used to keep track of the stopping status of one vector.

class StreamError

StreamError is thrown if accessing a stream failed.

· class temporary\_clone

A temporary\_clone is a special smart pointer-like object that is designed to hold an object temporarily copied to another executor.

· class Transposable

Linear operators which support transposition should implement the Transposable interface.

· class ValueMismatch

ValueMismatch is thrown if two values are not equal.

· struct version

This structure is used to represent versions of various Ginkgo modules.

· class version info

Ginkgo uses version numbers to label new features and to communicate backward compatibility guarantees:

· class WritableToMatrixData

A LinOp implementing this interface can write its data to a matrix\_data structure.

## **Typedefs**

• template<typename ConcreteFactory , typename ConcreteLinOp , typename ParametersType , typename PolymorphicBase = LinOp←Factory>

```
using EnableDefaultLinOpFactory = EnableDefaultFactory < ConcreteFactory, ConcreteLinOp, Parameters ← Type, PolymorphicBase >
```

This is an alias for the EnableDefaultFactory mixin, which correctly sets the template parameters to enable a subclass of LinOpFactory.

• template<typename T >

```
using remove_complex = typename detail::remove_complex_impl < T >::type
```

Obtains a real counterpart of a std::complex type, and leaves the type unchanged if it is not a complex type.

• template<typename T >

```
using is_complex_s = detail::is_complex_impl < T >
```

Allows to check if T is a complex value during compile time by accessing the value attribute of this struct.

template<typename T >

```
using reduce_precision = typename detail::reduce_precision_impl< T >::type
```

Obtains the next type in the hierarchy with lower precision than T.

template<typename T >

```
using increase_precision = typename detail::increase_precision_impl< T >::type
```

Obtains the next type in the hierarchy with higher precision than T.

template < typename T, size\_type Limit = sizeof(uint16) \* byte\_size>
 using truncate\_type = xstd::conditional\_t < detail::type\_size\_impl < T >::value >=2 \*Limit, typename detail ←

::truncate\_type\_impl< T >::type, T >

Truncates the type by half (by dropping bits), but ensures that it is at least Limit bits wide.

• using size type = std::size t

Integral type used for allocation quantities.

• using int8 = std::int8\_t

8-bit signed integral type.

• using int16 = std::int16 t

16-bit signed integral type.

• using int32 = std::int32\_t

32-bit signed integral type.

using int64 = std::int64\_t

64-bit signed integral type.

using uint8 = std::uint8\_t

8-bit unsigned integral type.

using uint16 = std::uint16\_t

```
16-bit unsigned integral type.
```

• using uint32 = std::uint32\_t

32-bit unsigned integral type.

using uint64 = std::uint64 t

64-bit unsigned integral type.

• using float16 = half

Half precision floating point type.

using float32 = float

Single precision floating point type.

• using float64 = double

Double precision floating point type.

• using full\_precision = double

The most precise floating-point type.

• using default\_precision = double

Precision used if no precision is explicitly specified.

#### **Enumerations**

enum layout\_type { layout\_type::array, layout\_type::coordinate }

Specifies the layout type when writing data in matrix market format.

#### **Functions**

```
    template<size_type Dimensionality, typename DimensionType >
    constexpr bool operator!= (const dim< Dimensionality, DimensionType > &x, const dim< Dimensionality,
    DimensionType > &y)
```

Checks if two dim objects are different.

 $\bullet \ \ \text{template}{<} \text{typename DimensionType} >$ 

```
constexpr \ dim < 2, \ Dimension Type > transpose \ (const \ dim < 2, \ Dimension Type > \& dimensions) \ no except
```

Returns a dim<2> object with its dimensions swapped.

template<typename T >

constexpr bool is\_complex ()

Checks if T is a complex type.

• template<typename T >

```
constexpr reduce precision < T > round down (T val)
```

Reduces the precision of the input parameter.

template<typename T >

```
constexpr increase_precision < T > round_up (T val)
```

Increases the precision of the input parameter.

constexpr int64 ceildiv (int64 num, int64 den)

Performs integer division with rounding up.

 $\bullet \;\; template\!<\! typename \; T>$ 

constexpr T zero ()

Returns the additive identity for T.

• template<typename T >

constexpr T zero (const T &)

Returns the additive identity for T.

• template<typename T >

constexpr T one ()

Returns the multiplicative identity for T.

```
• template<typename T >
  constexpr T one (const T &)
     Returns the multiplicative identity for T.

    template<typename T >

  constexpr T abs (const T &x)
      Returns the absolute value of the object.
• template<typename T >
  constexpr T max (const T &x, const T &y)
     Returns the larger of the arguments.

    template<typename T >

  constexpr T min (const T &x, const T &y)
     Returns the smaller of the arguments.

    template<typename T >

  constexpr T real (const T &x)
     Returns the real part of the object.
• template<typename T >
  constexpr T imag (const T &)
      Returns the imaginary part of the object.
• template<typename T >
  T conj (const T &x)
     Returns the conjugate of an object.

    template<typename T >

  constexpr auto squared norm (const T &x) -> decltype(real(conj(x) *x))
     Returns the squared norm of the object.
• template<typename T >
  constexpr uint32 get_significant_bit (const T &n, uint32 hint=0u) noexcept
      Returns the position of the most significant bit of the number.
template<typename T >
  constexpr T get_superior_power (const T &base, const T &limit, const T &hint=T{1}) noexcept
     Returns the smallest power of base not smaller than limit.
• template<typename T >
  xstd::enable if t< is complex s< T>::value, bool > isfinite (const T &value)
     Checks if all components of a complex value are finite, meaning they are neither +/- infinity nor NaN.
• template<typename ValueType = default_precision, typename IndexType = int32>
  matrix_data< ValueType, IndexType > read_raw (std::istream &is)
     Reads a matrix stored in matrix market format from an input stream.
• template<typename ValueType , typename IndexType >
  void write_raw (std::ostream &os, const matrix_data< ValueType, IndexType > &data, layout_type
  layout=layout_type::array)
      Writes a matrix_data structure to a stream in matrix market format.

    template<typename MatrixType , typename StreamType , typename... MatrixArgs>

  std::unique_ptr< MatrixType > read (StreamType &&is, MatrixArgs &&... args)
      Reads a matrix stored in matrix market format from an input stream.

    template<typename MatrixType , typename StreamType >

  void write (StreamType &&os, MatrixType *matrix, layout type layout=layout type::array)
      Reads a matrix stored in matrix market format from an input stream.
• template<typename R , typename T >
  std::unique_otr< R, std::function< void(R *)> > copy_and_convert_to (std::shared_ptr< const Executor >
  exec, T *obj)
     Converts the object to R and places it on Executor exec.
• template<typename R , typename T >
  std::unique_ptr< const R, std::function< void(const R *)> > copy_and_convert_to (std::shared_ptr< const
  Executor > exec, const T *obj)
```

Converts the object to R and places it on Executor exec.

template<typename R, typename T >
 std::shared\_ptr< R > copy\_and\_convert\_to (std::shared\_ptr< const Executor > exec, std::shared\_ptr< T >
 obj)

Converts the object to R and places it on Executor exec.

• template<typename R , typename T >

std::shared\_ptr< const R > copy\_and\_convert\_to (std::shared\_ptr< const Executor > exec, std::shared\_ \leftarrow ptr< const T > obj)

• constexpr bool operator== (precision\_reduction x, precision\_reduction y) noexcept

Checks if two precision\_reduction encodings are equal.

• constexpr bool operator!= (precision\_reduction x, precision\_reduction y) noexcept

Checks if two precision\_reduction encodings are different.

• template<typename Pointer >

detail::cloned\_type< Pointer > clone (const Pointer &p)

Creates a unique clone of the object pointed to by p.

 $\bullet \ \ \text{template}{<} \text{typename Pointer} >$ 

detail::cloned\_type< Pointer > clone (std::shared\_ptr< const Executor > exec, const Pointer &p)

Creates a unique clone of the object pointed to by p on Executor exec.

• template<typename OwningPointer >

detail::shared\_type< OwningPointer > share (OwningPointer &&p)

Marks the object pointed to by p as shared.

template<typename OwningPointer >

std::remove reference < OwningPointer >::type && give (OwningPointer &&p)

Marks that the object pointed to by p can be given to the callee.

template<typename Pointer >

std::enable\_if< detail::have\_ownership\_s< Pointer >::value, detail::pointee< Pointer > \* >::type lend (const Pointer &p)

Returns a non-owning (plain) pointer to the object pointed to by p.

template<typename Pointer >

 $std::enable\_if < !detail::have\_ownership\_s < Pointer > ::value, \ detail::pointee < Pointer > * > ::type \ lend \ (const Pointer \&p)$ 

Returns a non-owning (plain) pointer to the object pointed to by p.

• template<typename T , typename U >

```
std::decay< T >::type * as (U *obj)
```

Performs polymorphic type conversion.

• template<typename T , typename U >

```
const std::decay< T >::type * as (const U *obj)
```

Performs polymorphic type conversion.

• template<typename T >

```
temporary_clone < T > make_temporary_clone (std::shared_ptr < const Executor > exec, T *ptr)
```

Creates a temporary\_clone.

std::ostream & operator<< (std::ostream &os, const version &ver)</li>

Prints version information to a stream.

std::ostream & operator<< (std::ostream &os, const version\_info &ver\_info)</li>

Prints library version information in human-readable format to a stream.

• template<typename Matrix , typename... TArgs>

```
std::unique_ptr< Matrix > initialize (size_type stride, std::initializer_list< typename Matrix::value_type > vals, std::shared_ptr< const Executor > exec, TArgs &&... create_args)
```

Creates and initializes a column-vector.

template<typename Matrix , typename... TArgs>
 std::unique\_ptr< Matrix > initialize (std::initializer\_list< typename Matrix::value\_type > vals, std::shared\_
 ptr< const Executor > exec, TArgs &&... create args)

Creates and initializes a column-vector.

template<typename Matrix , typename... TArgs>
 std::unique\_ptr< Matrix > initialize (size\_type stride, std::initializer\_list< std::initializer\_list< typename
 Matrix::value\_type >> vals, std::shared\_ptr< const Executor > exec, TArgs &&... create\_args)

Creates and initializes a matrix.

template<typename Matrix , typename... TArgs>
 std::unique\_ptr< Matrix > initialize (std::initializer\_list< std::initializer\_list< typename Matrix::value\_type >>
 vals, std::shared\_ptr< const Executor > exec, TArgs &&... create\_args)

Creates and initializes a matrix.

- bool operator== (const stopping\_status &x, const stopping\_status &y) noexcept
  - Checks if two stopping statuses are equivalent.
- bool operator!= (const stopping\_status &x, const stopping\_status &y) noexcept

Checks if two stopping statuses are different.

## **Variables**

constexpr size\_type byte\_size = CHAR\_BIT
 Number of bits in a byte.

## 25.1.1 Detailed Description

The Ginkgo namespace.

## 25.1.2 Typedef Documentation

#### 25.1.2.1 is\_complex\_s

```
template<typename T >
using gko::is_complex_s = typedef detail::is_complex_impl<T>
```

Allows to check if T is a complex value during compile time by accessing the value attribute of this struct.

If value is true, T is a complex type, if it is false, T is not a complex type.

# **Template Parameters**

```
T type to check
```

# 25.1.3 Enumeration Type Documentation

#### 25.1.3.1 layout\_type

```
enum gko::layout_type [strong]
```

Specifies the layout type when writing data in matrix market format.

#### Enumerator

array	The matrix should be written as dense matrix in column-major order.
coordinate	The matrix should be written as a sparse matrix in coordinate format.

```
67 {
71 array,
75 coordinate
76 };
```

# 25.1.4 Function Documentation

#### 25.1.4.1 abs()

Returns the absolute value of the object.

## **Template Parameters**

```
T the type of the object
```

## **Parameters**

```
x the object
```

#### Returns

```
x >= zero<T>() ? x:-x;

363 {
364    return x >= zero<T>() ? x : -x;
365 }
```

# 25.1.4.2 as() [1/2]

```
template<typename T , typename U > const std::decay<T>::type* gko::as ( const U * obj ) [inline]
```

Performs polymorphic type conversion.

This is the constant version of the function.

# **Template Parameters**

Τ	requested result type
U	static type of the passed object

#### **Parameters**

```
obj the object which should be converted
```

#### Returns

If successful, returns a pointer to the subtype, otherwise throws NotSupported.

# 25.1.4.3 as() [2/2]

Performs polymorphic type conversion.

# **Template Parameters**

Т	requested result type
U	static type of the passed object

#### **Parameters**

ahi	the object which should be converted
UUI	i ille oblect willcii Siloulu be collverteu
,	<b>,</b>

# Returns

If successful, returns a pointer to the subtype, otherwise throws NotSupported.

# 25.1.4.4 ceildiv()

Performs integer division with rounding up.

#### **Parameters**

num	numerator
den	denominator

#### Returns

returns the ceiled quotient.

Referenced by  $gko::preconditioner::block_interleaved_storage_scheme < index_type >::compute_storage_ <math>\leftarrow$  space().

## 25.1.4.5 clone() [1/2]

Creates a unique clone of the object pointed to by p.

The pointee (i.e. \*p) needs to have a clone method that returns a std::unique\_ptr in order for this method to work.

#### **Template Parameters**

Pointer	type of pointer to the object (plain or smart pointer)
---------	--

#### **Parameters**

```
p a pointer to the object
```

#### Note

The difference between this function and directly calling LinOp::clone() is that this one preserves the static type of the object.

Referenced by gko::temporary\_clone < T >::temporary\_clone().

#### 25.1.4.6 clone() [2/2]

Creates a unique clone of the object pointed to by p on Executor exec.

The pointee (i.e. \*p) needs to have a clone method that takes an executor and returns a std::unique\_ptr in order for this method to work.

## **Template Parameters**

Pointer	type of pointer to the object (plain or smart pointer)
---------	--

#### **Parameters**

exec	the executor where the cloned object should be stored
р	a pointer to the object

#### Note

The difference between this function and directly calling LinOp::clone() is that this one preserves the static type of the object.

## 25.1.4.7 conj()

Returns the conjugate of an object.

#### **Parameters**

```
x the number to conjugate
```

## Returns

conjugate of the object (by default, the object itself)

Referenced by squared\_norm().

# 25.1.4.8 copy\_and\_convert\_to() [1/4]

Converts the object to R and places it on Executor exec.

If the object is already of the requested type and on the requested executor, the copy and conversion is avoided and a reference to the original object is returned instead.

## **Template Parameters**

	the type to which the object should be converted
Т	the type of the input object

#### **Parameters**

exec	the executor where the result should be placed
obj	the object that should be converted

## Returns

a unique pointer (with dynamically bound deleter) to the converted object

#### Note

This is a version of the function which adds the const qualifier to the result if the input had the same qualifier.

#### 25.1.4.9 copy\_and\_convert\_to() [2/4]

This is the version that takes in the std::shared\_ptr and returns a std::shared\_ptr

If the object is already of the requested type and on the requested executor, the copy and conversion is avoided and a reference to the original object is returned instead.

#### **Template Parameters**

R	the type to which the object should be converted
T	the type of the input object

# **Parameters**

exec	the executor where the result should be placed
obj	the object that should be converted

#### Returns

a shared pointer to the converted object

#### Note

This is a version of the function which adds the const qualifier to the result if the input had the same qualifier.

## 25.1.4.10 copy\_and\_convert\_to() [3/4]

Converts the object to R and places it on Executor exec.

This is the version that takes in the std::shared\_ptr and returns a std::shared\_ptr

If the object is already of the requested type and on the requested executor, the copy and conversion is avoided and a reference to the original object is returned instead.

## **Template Parameters**

R	the type to which the object should be converted
T	the type of the input object

#### **Parameters**

	exec	the executor where the result should be placed
ĺ	obj	the object that should be converted

#### Returns

a shared pointer to the converted object

## 25.1.4.11 copy\_and\_convert\_to() [4/4]

Converts the object to R and places it on Executor exec.

If the object is already of the requested type and on the requested executor, the copy and conversion is avoided and a reference to the original object is returned instead.

#### **Template Parameters**

R	the type to which the object should be converted	
Т	the type of the input object	t

#### **Parameters**

exec	the executor where the result should be placed
obj	the object that should be converted

#### Returns

a unique pointer (with dynamically bound deleter) to the converted object

#### 25.1.4.12 get\_significant\_bit()

Returns the position of the most significant bit of the number.

This is the same as the rounded down base-2 logarithm of the number.

#### **Template Parameters**

7	Τ	a numeric type supporting bit shift and comparison

## **Parameters**

n	a number
hint	a lower bound for the position o the significant bit

#### Returns

maximum of  $\mbox{hint}$  and the significant bit position of  $\mbox{n}$ 

## 25.1.4.13 get\_superior\_power()

Returns the smallest power of base not smaller than limit.

# **Template Parameters**

```
T a numeric type supporting multiplication and comparison
```

#### **Parameters**

base	the base of the power to be returned
limit	the lower limit on the size of the power returned
hint	a lower bound on the result, has to be a power of base

## Returns

the smallest power of base not smaller than limit

# 25.1.4.14 give()

Marks that the object pointed to by p can be given to the callee.

Effectively calls std::move(p).

# **Template Parameters**

OwninaPointer	type of pointer with ownership to the object (has to be a smart pointer)
OwningPointer	type of pointer with ownership to the object that to be a smart point

# **Parameters**

```
p a pointer to the object
```

# Note

The original pointer  $\ensuremath{p}$  becomes invalid after this call.

## 25.1.4.15 imag()

Returns the imaginary part of the object.

# **Template Parameters**

```
T | type of the object
```

#### **Parameters**

```
x the object
```

#### Returns

imaginary part of the object (by default, zero<T>())

# 25.1.4.16 is\_complex()

```
template<typename T >
constexpr bool gko::is_complex ( ) [inline], [constexpr]
```

Checks if T is a complex type.

#### **Template Parameters**

```
T type to check
```

#### Returns

true if T is a complex type, false otherwise

# 25.1.4.17 isfinite()

Checks if all components of a complex value are finite, meaning they are neither +/- infinity nor NaN.

#### **Template Parameters**

T complex type of the value to check

## **Parameters**

value	complex value to check
-------	------------------------

returns true if both components of the given value are finite, meaning they are neither +/- infinity nor NaN.

## 25.1.4.18 lend() [1/2]

Returns a non-owning (plain) pointer to the object pointed to by p.

#### **Template Parameters**

Pointer	type of pointer to the object (plain or smart pointer)
---------	--

#### **Parameters**

```
p a pointer to the object
```

#### Note

This is the overload for owning (smart) pointers, that behaves the same as calling .get() on the smart pointer.

Referenced by gko::log::EnableLogging < Executor >::remove\_logger().

# 25.1.4.19 lend() [2/2]

Returns a non-owning (plain) pointer to the object pointed to by p.

## **Template Parameters**

Pointer	type of pointer to the object (plain or smart pointer)
---------	--

#### **Parameters**

```
p a pointer to the object
```

#### Note

This is the overload for non-owning (plain) pointers, that just returns p.

## 25.1.4.20 make\_temporary\_clone()

Creates a temporary clone.

This is a helper function which avoids the need to explicitly specify the type of the object, as would be the case if using the constructor of temporary\_clone.

#### **Parameters**

ехес	the executor where the clone will be created
ptr	a pointer to the object of which the clone will be created

Referenced by gko::matrix::Dense< ValueType >::add\_scaled(), gko::matrix::Coo< ValueType, IndexType > $\leftarrow$  ::apply2(), gko::matrix::Dense< ValueType >::compute\_dot(), gko::matrix::Dense< ValueType >::compute\_ $\leftarrow$  norm2(), and gko::matrix::Dense< ValueType >::scale().

#### 25.1.4.21 max()

Returns the larger of the arguments.

#### **Template Parameters**

#### **Parameters**

Х	first argument
У	second argument

#### Returns

$$x >= y ? x : y$$

Note

C++11 version of this function is not constexpr, thus we provide our own implementation.

## 25.1.4.22 min()

Returns the smaller of the arguments.

#### **Template Parameters**

T	type of the arguments
---	-----------------------

## **Parameters**

Х	first argument
у	second argument

#### Returns

```
x \le y ? x : y
```

Note

C++11 version of this function is not constexpr, thus we provide our own implementation.

# 25.1.4.23 one() [1/2]

```
template<typename T >
constexpr T gko::one ( ) [inline], [constexpr]
```

Returns the multiplicative identity for T.

Returns

the multiplicative identity for T

# 25.1.4.24 one() [2/2]

Returns the multiplicative identity for T.

Returns

the multiplicative identity for T

Note

This version takes an unused reference argument to avoid complicated calls like one < decltype(x) > (). Instead, it allows one(x).

#### 25.1.4.25 operator"!=() [1/3]

Checks if two dim objects are different.

#### **Template Parameters**

Dimensionality	number of dimensions of the dim objects
DimensionType	datatype used to represent each dimension

#### **Parameters**

Х	first object
у	second object

#### Returns

```
! (x == y)

219 {
220    return ! (x == y);
221 }
```

## 25.1.4.26 operator"!=() [2/3]

Checks if two stopping statuses are different.

#### **Parameters**

X	a stopping status
У	a stopping status

#### Returns

```
true if and only if ! (x == y)

179 {
180     return x.data_ != y.data_;
181 }
```

## 25.1.4.27 operator"!=() [3/3]

Checks if two precision\_reduction encodings are different.

#### **Parameters**

Х	an encoding
у	an encoding

#### Returns

true if and only if x and y are different encodings.

```
368 {
369     using st = precision_reduction::storage_type;
370     return static_cast<st>(x) != static_cast<st>(y);
371 }
```

## 25.1.4.28 operator << () [1/2]

Prints version information to a stream.

#### **Parameters**

	os	output stream
ſ	ver	version structure

#### Returns

```
OS

115 {
116         os « ver.major « "." « ver.minor « "." « ver.patch;
117         if (ver.tag) {
118             os « " (" « ver.tag « ")";
119         }
120         return os;
```

References gko::version::major, gko::version::minor, gko::version::patch, and gko::version::tag.

#### 25.1.4.29 operator << () [2/2]

Prints library version information in human-readable format to a stream.

#### **Parameters**

os	output stream
ver_info	version information

## Returns

os

## 25.1.4.30 operator==() [1/2]

Checks if two stopping statuses are equivalent.

#### **Parameters**

X	a stopping status
У	a stopping status

## Returns

true if and only if both  $\boldsymbol{x}$  and  $\boldsymbol{y}$  have the same mask and converged and finalized state

# 25.1.4.31 operator==() [2/2]

Checks if two precision\_reduction encodings are equal.

## Parameters

X	an encoding
У	an encoding

# Returns

true if and only if  $\boldsymbol{x}$  and  $\boldsymbol{y}$  are the same encodings

#### 25.1.4.32 read()

Reads a matrix stored in matrix market format from an input stream.

#### **Template Parameters**

MatrixType	a ReadableFromMatrixData LinOp type used to store the matrix once it's been read from disk.	
StreamType	type of stream used to write the data to	
MatrixArgs additional argument types passed to MatrixType constructor		

#### **Parameters**

is	input stream from which to read the data
args	additional arguments passed to MatrixType constructor

#### Returns

A MatrixType LinOp filled with data from filename

References read\_raw().

## 25.1.4.33 read\_raw()

Reads a matrix stored in matrix market format from an input stream.

## **Template Parameters**

ValueType	type of matrix values
IndexType	type of matrix indexes

#### **Parameters**

ic	input stream from which to read the data
10	input stream nom winer to read the data

## Returns

A matrix\_data structure containing the matrix. The nonzero elements are sorted in lexicographic order of their (row, colum) indexes.

Note

This is an advanced routine that will return the raw matrix data structure. Consider using gko::read instead.

Referenced by read().

# 25.1.4.34 real()

Returns the real part of the object.

# **Template Parameters**

```
T type of the object
```

#### **Parameters**

```
x the object
```

## Returns

real part of the object (by default, the object itself)

Referenced by squared\_norm().

# 25.1.4.35 round\_down()

Reduces the precision of the input parameter.

## **Template Parameters**

```
T the original precision
```

#### **Parameters**

val the value to round down

#### Returns

the rounded down value

#### 25.1.4.36 round\_up()

```
template<typename T >
constexpr increase_precision<T> gko::round_up (
          T val ) [inline], [constexpr]
```

Increases the precision of the input parameter.

**Template Parameters** 

```
T the original precision
```

#### **Parameters**

```
val the value to round up
```

#### Returns

the rounded up value

#### 25.1.4.37 share()

Marks the object pointed to by p as shared.

Effectively converts a pointer with ownership to std::shared\_ptr.

## **Template Parameters**

OwningPointer type of pointer with ownership to the object (has to be a smart pointer)

#### **Parameters**

p a pointer to the object

Note

The original pointer  $\ensuremath{p}$  becomes invalid after this call.

#### 25.1.4.38 squared\_norm()

```
\label{template} $$ \ensuremath{\sf template}$ $$ \ensurem
```

Returns the squared norm of the object.

**Template Parameters** 

```
T type of the object.
```

#### Returns

The squared norm of the object.

References conj(), and real().

#### 25.1.4.39 transpose()

Returns a dim<2> object with its dimensions swapped.

### **Template Parameters**

DimensionType	datatype used to represent each dimension

#### **Parameters**

dimensions	original object

#### Returns

a dim<2> object with its dimensions swapped

#### 25.1.4.40 write()

Reads a matrix stored in matrix market format from an input stream.

#### **Template Parameters**

MatrixType	a ReadableFromMatrixData LinOp type used to store the matrix once it's been read from disk.
StreamType	type of stream used to write the data to

#### **Parameters**

os	output stream where the data is to be written
matrix	the matrix to write
layout	the layout used in the output

References write\_raw().

#### 25.1.4.41 write\_raw()

Writes a matrix\_data structure to a stream in matrix market format.

#### **Template Parameters**

ValueType	type of matrix values
IndexType	type of matrix indexes

#### **Parameters**

os	output stream where the data is to be written
data	the matrix data to write
layout	the layout used in the output

#### Note

This is an advanced routine that writes the raw matrix data structure. If you are trying to write an existing matrix, consider using gko::write instead.

Referenced by write().

#### 25.1.4.42 zero() [1/2]

```
template<typename T >
constexpr T gko::zero ( ) [inline], [constexpr]
```

Returns the additive identity for T.

Returns

additive identity for T

#### 25.1.4.43 zero() [2/2]

Returns the additive identity for T.

Returns

additive identity for T

Note

This version takes an unused reference argument to avoid complicated calls like zero < decltype(x) > (). Instead, it allows zero(x).

## 25.2 gko::accessor Namespace Reference

The accessor namespace.

#### Classes

· class row\_major

A row\_major accessor is a bridge between a range and the row-major memory layout.

## 25.2.1 Detailed Description

The accessor namespace.

## 25.3 gko::factorization Namespace Reference

The Factorization namespace.

#### **Classes**

· class Parllu

ParILU is an incomplete LU factorization which is computed in parallel.

## 25.3.1 Detailed Description

The Factorization namespace.

## 25.4 gko::log Namespace Reference

The logger namespace.

#### Classes

· class Convergence

Convergence is a Logger which logs data strictly from the criterion\_check\_completed event.

· struct criterion\_data

Struct representing Criterion related data.

class EnableLogging

EnableLogging is a mixin which should be inherited by any class which wants to enable logging.

· struct executor data

Struct representing Executor related data.

· struct iteration\_complete\_data

Struct representing iteration complete related data.

struct linop\_data

Struct representing LinOp related data.

struct linop\_factory\_data

Struct representing LinOp factory related data.

class Loggable

Loggable class is an interface which should be implemented by classes wanting to support logging.

struct operation\_data

Struct representing Operator related data.

· struct polymorphic object data

Struct representing PolymorphicObject related data.

· class Record

Record is a Logger which logs every event to an object.

class Stream

Stream is a Logger which logs every event to a stream.

#### 25.4.1 Detailed Description

The logger namespace.

The Logging namespace.

Logging

## 25.5 gko::matrix Namespace Reference

The matrix namespace.

#### Classes

· class Coo

COO stores a matrix in the coordinate matrix format.

· class Csr

CSR is a matrix format which stores only the nonzero coefficients by compressing each row of the matrix (compressed sparse row format).

class Dense

Dense is a matrix format which explicitly stores all values of the matrix.

class Ell

ELL is a matrix format where stride with explicit zeros is used such that all rows have the same number of stored elements.

· class Hybrid

HYBRID is a matrix format which splits the matrix into ELLPACK and COO format.

· class Identity

This class is a utility which efficiently implements the identity matrix (a linear operator which maps each vector to itself).

· class IdentityFactory

This factory is a utility which can be used to generate Identity operators.

· class Sellp

SELL-P is a matrix format similar to ELL format.

class SparsityCsr

SparsityCsr is a matrix format which stores only the sparsity pattern of a sparse matrix by compressing each row of the matrix (compressed sparse row format).

#### 25.5.1 Detailed Description

The matrix namespace.

## 25.6 gko::name\_demangling Namespace Reference

The name demangling namespace.

#### **Functions**

```
    template<typename T >
        std::string get_static_type (const T &)
```

This function uses name demangling facilities to get the name of the static type (T) of the object passed in arguments.

template<typename T >
 std::string get\_dynamic\_type (const T &t)

This function uses name demangling facilities to get the name of the dynamic type of the object passed in arguments.

## 25.6.1 Detailed Description

The name demangling namespace.

#### 25.6.2 Function Documentation

#### 25.6.2.1 get\_dynamic\_type()

This function uses name demangling facilities to get the name of the dynamic type of the object passed in arguments.

#### **Template Parameters**

```
T the type of the object to demangle
```

#### **Parameters**

 $t \mid$  the object we get the dynamic type of

#### 25.6.2.2 get\_static\_type()

This function uses name demangling facilities to get the name of the static type (T) of the object passed in arguments.

**Template Parameters** 

the type of the object to demangle

**Parameters** 

unused

## 25.7 gko::preconditioner Namespace Reference

The Preconditioner namespace.

#### **Classes**

· struct block interleaved storage scheme

Defines the parameters of the interleaved block storage scheme used by block-Jacobi blocks.

class IIu

The Incomplete LU (ILU) preconditioner solves the equation LUx=b for a given lower triangular matrix L, an upper triangular matrix U and the right hand side b (can contain multiple right hand sides).

· class Jacobi

A block-Jacobi preconditioner is a block-diagonal linear operator, obtained by inverting the diagonal blocks of the source operator.

#### 25.7.1 Detailed Description

The Preconditioner namespace.

## 25.8 gko::solver Namespace Reference

The ginkgo Solve namespace.

#### **Classes**

· class Bicgstab

BiCGSTAB or the Bi-Conjugate Gradient-Stabilized is a Krylov subspace solver.

class Co

CG or the conjugate gradient method is an iterative type Krylov subspace method which is suitable for symmetric positive definite methods.

• class Cgs

CGS or the conjugate gradient square method is an iterative type Krylov subspace method which is suitable for general systems.

class Fcg

FCG or the flexible conjugate gradient method is an iterative type Krylov subspace method which is suitable for symmetric positive definite methods.

· class Gmres

GMRES or the generalized minimal residual method is an iterative type Krylov subspace method which is suitable for nonsymmetric linear systems.

· class Ir

Iterative refinement (IR) is an iterative method that uses another coarse method to approximate the error of the current solution via the current residual.

class LowerTrs

LowerTrs is the triangular solver which solves the system L x = b, when L is a lower triangular matrix.

class UpperTrs

UpperTrs is the triangular solver which solves the system U x = b, when U is an upper triangular matrix.

#### 25.8.1 Detailed Description

The ginkgo Solve namespace.

## 25.9 gko::stop Namespace Reference

The Stopping criterion namespace.

#### Classes

· class Combined

The Combined class is used to combine multiple criterions together through an OR operation.

· class Criterion

The Criterion class is a base class for all stopping criteria.

struct CriterionArgs

This struct is used to pass parameters to the EnableDefaultCriterionFactoryCriterionFactory::generate() method.

class Iteration

The Iteration class is a stopping criterion which stops the iteration process after a preset number of iterations.

• class ResidualNormReduction

The ResidualNormReduction class is a stopping criterion which stops the iteration process when the relative residual norm is below a certain threshold.

class Time

The Time class is a stopping criterion which stops the iteration process after a certain amout of time has passed.

## **Typedefs**

using CriterionFactory = AbstractFactory < Criterion, CriterionArgs >

Declares an Abstract Factory specialized for Criterions.

• template<typename ConcreteFactory , typename ConcreteCriterion , typename ParametersType , typename PolymorphicBase = CriterionFactory>

using EnableDefaultCriterionFactory = EnableDefaultFactory< ConcreteFactory, ConcreteCriterion, ParametersType, PolymorphicBase >

This is an alias for the EnableDefaultFactory mixin, which correctly sets the template parameters to enable a subclass of CriterionFactory.

#### **Functions**

template < typename FactoryContainer >
 std::shared\_ptr < const CriterionFactory > combine (FactoryContainer &&factories)
 Combines multiple criterion factories into a single combined criterion factory.

#### 25.9.1 Detailed Description

The Stopping criterion namespace.

Stopping criteria

## 25.9.2 Typedef Documentation

#### 25.9.2.1 EnableDefaultCriterionFactory

```
template<typename ConcreteFactory , typename ConcreteCriterion , typename ParametersType ,
typename PolymorphicBase = CriterionFactory>
using gko::stop::EnableDefaultCriterionFactory = typedef EnableDefaultFactory<ConcreteFactory,
ConcreteCriterion, ParametersType, PolymorphicBase>
```

This is an alias for the EnableDefaultFactory mixin, which correctly sets the template parameters to enable a subclass of CriterionFactory.

#### **Template Parameters**

ConcreteFactory	the concrete factory which is being implemented [CRTP parmeter]
ConcreteCriterion	the concrete Criterion type which this factory produces, needs to have a constructor which takes a const ConcreteFactory *, and a const CriterionArgs * as parameters.
ParametersType	a subclass of enable_parameters_type template which defines all of the parameters of the factory
PolymorphicBase	parent of ConcreteFactory in the polymorphic hierarchy, has to be a subclass of CriterionFactory

# 26.1 gko::AbstractFactory< AbstractProductType, ComponentsType > Class Template Reference

The AbstractFactory is a generic interface template that enables easy implementation of the abstract factory design pattern.

#include <ginkgo/core/base/abstract\_factory.hpp>

#### **Public Member Functions**

template<typename... Args>
 std::unique\_ptr< AbstractProductType > generate (Args &&... args) const
 Creates a new product from the given components.

#### 26.1.1 Detailed Description

template < typename AbstractProductType, typename ComponentsType > class gko::AbstractFactory < AbstractProductType, ComponentsType >

The AbstractFactory is a generic interface template that enables easy implementation of the abstract factory design pattern.

The interface provides the AbstractFactory::generate() method that can produce products of type Abstract ProductType using an object of ComponentsType (which can be constructed on the fly from parameters to its constructors). The generate() method is not declared as virtual, as this allows subclasses to hide the method with a variant that preserves the compile-time type of the objects. Instead, implementers should override the generate impl() method, which is declared virtual.

Implementers of concrete factories should consider using the EnableDefaultFactory mixin to obtain default implementations of utility methods of PolymorphicObject and AbstractFactory.

#### **Template Parameters**

AbstractProductType	the type of products the factory produces
ComponentsType	the type of components the factory needs to produce the product

#### 26.1.2 Member Function Documentation

#### 26.1.2.1 generate()

Creates a new product from the given components.

The method will create an ComponentsType object from the arguments of this method, and pass it to the generate ← \_impl() function which will create a new AbstractProductType.

#### **Template Parameters**

Args types of arguments passed to the constructor of ComponentsType

#### **Parameters**

args	arguments passed to the constructor of ComponentsType
------	---

#### Returns

an instance of AbstractProductType

```
93  {
94      auto product = this->generate_impl({std::forward<Args>(args)...});
95      for (auto logger : this->loggers_) {
96          product->add_logger(logger);
97      }
98      return product;
99    }
```

The documentation for this class was generated from the following file:

• ginkgo/core/base/abstract\_factory.hpp (97addc067)

## 26.2 gko::AllocationError Class Reference

AllocationError is thrown if a memory allocation fails.

```
#include <ginkgo/core/base/exception.hpp>
```

#### **Public Member Functions**

AllocationError (const std::string &file, int line, const std::string &device, size\_type bytes)
 Initializes an allocation error.

#### 26.2.1 Detailed Description

AllocationError is thrown if a memory allocation fails.

#### 26.2.2 Constructor & Destructor Documentation

#### 26.2.2.1 AllocationError()

Initializes an allocation error.

#### **Parameters**

file	The name of the offending source file
line	The source code line number where the error occurred
device	The device on which the error occurred
bytes	The size of the memory block whose allocation failed.

```
348 : Error(file, line,
349 device + ": failed to allocate memory block of " +
350 std::to_string(bytes) + "B")
351 {}
```

The documentation for this class was generated from the following file:

• ginkgo/core/base/exception.hpp (6e8865457)

## 26.3 gko::Array< ValueType > Class Template Reference

An Array is a container which encapsulates fixed-sized arrays, stored on the Executor tied to the Array.

```
#include <ginkgo/core/base/array.hpp>
```

#### **Public Types**

using value\_type = ValueType

The type of elements stored in the array.

using default\_deleter = executor\_deleter < value\_type[]>

The default deleter type used by Array.

using view\_deleter = null\_deleter < value\_type[]>

The deleter type used for views.

#### **Public Member Functions**

· Array () noexcept

Creates an empty Array not tied to any executor.

Array (std::shared ptr< const Executor > exec) noexcept

Creates an empty Array tied to the specified Executor.

Array (std::shared\_ptr< const Executor > exec, size\_type num\_elems)

Creates an Array on the specified Executor.

template<typename DeleterType >

Array (std::shared\_ptr< const Executor > exec, size\_type num\_elems, value\_type \*data, DeleterType deleter)

Creates an Array from existing memory.

• Array (std::shared\_ptr< const Executor > exec, size\_type num\_elems, value\_type \*data)

Creates an Array from existing memory.

template<typename RandomAccessIterator >

Array (std::shared\_ptr< const Executor > exec, RandomAccessIterator begin, RandomAccessIterator end)

Creates an array on the specified Executor and initializes it with values.

template<typename T >

Array (std::shared ptr< const Executor > exec, std::initializer list< T > init list)

Creates an array on the specified Executor and initializes it with values.

Array (std::shared\_ptr< const Executor > exec, const Array &other)

Creates a copy of another array on a different executor.

• Array (const Array &other)

Creates a copy of another array.

Array (std::shared\_ptr< const Executor > exec, Array &&other)

Moves another array to a different executor.

• Array (Array &&other)

Moves another array.

Array & operator= (const Array & other)

Copies data from another array.

Array & operator= (Array &&other)

Moves data from another array.

• void clear () noexcept

Deallocates all data used by the Array.

void resize\_and\_reset (size\_type num\_elems)

Resizes the array so it is able to hold the specified number of elements.

• size\_type get\_num\_elems () const noexcept

Returns the number of elements in the Array.

value\_type \* get\_data () noexcept

Returns a pointer to the block of memory used to store the elements of the Array.

const value type \* get const data () const noexcept

Returns a constant pointer to the block of memory used to store the elements of the Array.

std::shared\_ptr< const Executor > get\_executor () const noexcept

Returns the Executor associated with the array.

void set\_executor (std::shared\_ptr< const Executor > exec)

Changes the Executor of the Array, moving the allocated data to the new Executor.

#### **Static Public Member Functions**

• static Array view (std::shared\_ptr< const Executor > exec, size\_type num\_elems, value\_type \*data)

Creates an Array from existing memory.

#### 26.3.1 Detailed Description

```
template<typename ValueType> class gko::Array< ValueType>
```

An Array is a container which encapsulates fixed-sized arrays, stored on the Executor tied to the Array.

The array stores and transfers its data as **raw** memory, which means that the constructors of its elements are not called when constructing, copying or moving the Array. Thus, the Array class is most suitable for storing POD types.

#### **Template Parameters**

ValueType	the type of elements stored in the array
-----------	--

#### 26.3.2 Constructor & Destructor Documentation

#### 26.3.2.1 Array() [1/11]

```
template<typename ValueType>
gko::Array< ValueType >::Array ( ) [inline], [noexcept]
```

Creates an empty Array not tied to any executor.

An array without an assigned executor can only be empty. Attempts to change its size (e.g. via the resize\_and\_\circ} reset method) will result in an exception. If such an array is used as the right hand side of an assignment or move assignment expression, the data of the target array will be cleared, but its executor will not be modified.

The executor can later be set by using the set\_executor method. If an Array with no assigned executor is assigned or moved to, it will inherit the executor of the source Array.

```
94 : num_elems_(0),

95 data_(nullptr, default_deleter{nullptr}),

96 exec_(nullptr)

97 {}
```

#### 26.3.2.2 Array() [2/11]

Creates an empty Array tied to the specified Executor.

#### **Parameters**

```
exec the Executor where the array data is allocated
```

#### 26.3.2.3 Array() [3/11]

Creates an Array on the specified Executor.

#### **Parameters**

exec	the Executor where the array data will be allocated
num_elems	the amount of memory (expressed as the number of value_type elements) allocated on the
	Executor

#### 26.3.2.4 Array() [4/11]

Creates an Array from existing memory.

The memory will be managed by the array, and deallocated using the specified deleter (e.g. use std::default\_delete for data allocated with new).

#### **Template Parameters**

#### **Parameters**

exec	executor where data is located
num_elems	number of elements in data
data	chunk of memory used to create the array
deleter	the deleter used to free the memory

#### See also

Array::view() to create an array that does not deallocate memory

 $\label{lem:array} Array(std::shared\_ptr < cont Executor>, size\_type, value\_type*) to deallocate the memory using \\ \underline{Executor::free()} \ method$ 

#### 26.3.2.5 Array() [5/11]

Creates an Array from existing memory.

The memory will be managed by the array, and deallocated using the Executor::free method.

#### **Parameters**

exec	executor where data is located
num_elems	number of elements in data
data	chunk of memory used to create the array

#### 26.3.2.6 Array() [6/11]

Creates an array on the specified Executor and initializes it with values.

#### **Template Parameters**

RandomAccessIterator	type of the iterators
----------------------	-----------------------

#### **Parameters**

exec	the Executor where the array data will be allocated
begin	start of range of values
end	end of range of values

#### 26.3.2.7 Array() [7/11]

```
template<typename ValueType>
template<typename T >
```

Creates an array on the specified Executor and initializes it with values.

#### **Template Parameters**

```
T | type of values used to initialize the array (T has to be implicitly convertible to value_type)
```

#### **Parameters**

exec	the Executor where the array data will be allocated
init_list	list of values used to initialize the Array

#### 26.3.2.8 Array() [8/11]

Creates a copy of another array on a different executor.

This does not invoke the constructors of the elements, instead they are copied as POD types.

#### **Parameters**

ехес	the executor where the new array will be created
other	the Array to copy from

#### 26.3.2.9 Array() [9/11]

Creates a copy of another array.

This does not invoke the constructors of the elements, instead they are copied as POD types.

#### **Parameters**

other	the Array to copy from
-------	------------------------

#### 26.3.2.10 Array() [10/11]

Moves another array to a different executor.

This does not invoke the constructors of the elements, instead they are copied as POD types.

#### **Parameters**

exec	the executor where the new array will be moved
other	the Array to move

#### 26.3.2.11 Array() [11/11]

Moves another array.

This does not invoke the constructors of the elements, instead they are copied as POD types.

#### **Parameters**

other	the Array to move

#### 26.3.3 Member Function Documentation

## 26.3.3.1 clear()

```
template<typename ValueType>
void gko::Array< ValueType >::clear ( ) [inline], [noexcept]
```

Deallocates all data used by the Array.

The array is left in a valid, but empty state, so the same array can be used to allocate new memory. Calls to Array::get\_data() will return a nullptr.

#### 26.3.3.2 get\_const\_data()

```
template<typename ValueType>
const value_type* gko::Array< ValueType >::get_const_data ( ) const [inline], [noexcept]
```

Returns a constant pointer to the block of memory used to store the elements of the Array.

#### Returns

a constant pointer to the block of memory used to store the elements of the Array

#### 26.3.3.3 get data()

```
template<typename ValueType>
value_type* gko::Array< ValueType >::get_data ( ) [inline], [noexcept]
```

Returns a pointer to the block of memory used to store the elements of the Array.

#### Returns

a pointer to the block of memory used to store the elements of the Array

Referenced by gko::matrix::Dense < ValueType >::at(), gko::matrix::Hybrid < ValueType, IndexType >::imbalance - limit::compute\_ell\_num\_stored\_elements\_per\_row(), gko::matrix::Sellp < ValueType, IndexType >::get\_col\_idxs(), gko::matrix::SparsityCsr < ValueType, IndexType >::get\_col\_idxs(), gko::matrix::Ell < ValueType, IndexType >::get\_col\_idxs(), gko::matrix::Csr < ValueType, IndexType >::get\_col\_idxs(), gko::matrix::Csr < ValueType, IndexType >::get\_row\_idxs(), gko::matrix::SparsityCsr < ValueType, IndexType >::get\_row\_ptrs(), gko::matrix::Csr < ValueType, IndexType >::get\_row\_ptrs(), gko::matrix::Csr < ValueType, IndexType >::get\_row\_ptrs(), gko::matrix::Sellp < ValueType, IndexType >::get\_slice\_engths(), gko::matrix::SparsityCsr < ValueType, IndexType >::get\_value(), gko::matrix::Sellp < ValueType, IndexType >::get\_valueType, IndexType >::get\_valueS(), gko::matrix::Ell < ValueType, IndexElle >::get\_valueS(), gko::matrix::Dense < ValueType, IndexType >::val\_at(), gko::matrix::Dense < ValueTy

#### 26.3.3.4 get\_executor()

```
template<typename ValueType>
std::shared_ptr<const Executor> gko::Array< ValueType >::get_executor ( ) const [inline],
[noexcept]
```

Returns the Executor associated with the array.

#### Returns

the Executor associated with the array

Referenced by gko::matrix::Hybrid< ValueType, IndexType >::strategy\_type::compute\_hybrid\_config(), and gko :::Array< index\_type >::operator=().

#### 26.3.3.5 get\_num\_elems()

```
template<typename ValueType>
size_type gko::Array< ValueType >::get_num_elems ( ) const [inline], [noexcept]
```

Returns the number of elements in the Array.

#### Returns

the number of elements in the Array

Referenced by gko::matrix::Hybrid< ValueType, IndexType >::imbalance\_limit::compute\_ell\_num\_stored\_  $\leftarrow$  elements\_per\_row(), gko::matrix::Hybrid< ValueType, IndexType >::imbalance\_bounded\_limit::compute\_ell  $\leftarrow$  \_num\_stored\_elements\_per\_row(), gko::matrix::Hybrid< ValueType, IndexType >::strategy\_type::compute\_  $\leftarrow$  hybrid\_config(), gko::matrix::SparsityCsr< ValueType, IndexType >::get\_num\_nonzeros(), gko::matrix::Csr< ValueType, IndexType >::get\_num\_srow\_elements(), gko::matrix::Ell< ValueType, IndexType >::get\_num\_  $\leftarrow$  stored\_elements(), gko::matrix::Coo< ValueType, IndexType >::get\_num\_stored\_elements(), gko::matrix::Dense< ValueType >::get\_num\_stored\_  $\leftarrow$  elements(), gko::preconditioner::Jacobi< ValueType, IndexType >::get\_num\_stored\_elements(), gko::matrix::Csr< ValueType, IndexType >::get\_num\_stored\_elements(), and gko::Array< index\_type >::operator=().

#### 26.3.3.6 operator=() [1/2]

Moves data from another array.

This does not invoke the constructors of the elements, instead they are copied as POD types.

The executor of this is preserved. In case this does not have an assigned executor, it will inherit the executor of other.

#### **Parameters**

other the Array to move data from

#### Returns

this

#### 26.3.3.7 operator=() [2/2]

Copies data from another array.

This does not invoke the constructors of the elements, instead they are copied as POD types.

The executor of this is preserved. In case this does not have an assigned executor, it will inherit the executor of other.

#### **Parameters**

other the Array to copy from

## Returns

this

#### 26.3.3.8 resize\_and\_reset()

Resizes the array so it is able to hold the specified number of elements.

All data stored in the array will be lost.

If the Array is not assigned an executor, an exception will be thrown.

#### **Parameters**

num_elems	the amount of memory (expressed as the number of value_type elements) allocated on the
	Executor

Referenced by gko::Array< index\_type >::operator=().

#### 26.3.3.9 set executor()

Changes the Executor of the Array, moving the allocated data to the new Executor.

#### **Parameters**

the data will be moved to	exec the Executor where
---------------------------	-------------------------

#### 26.3.3.10 view()

Creates an Array from existing memory.

The Array does not take ownership of the memory, and will not deallocate it once it goes out of scope.

#### **Parameters**

exec	executor where data is located
num_elems	number of elements in data
data	chunk of memory used to create the array

#### Returns

an Array constructed from data

Referenced by gko::matrix::Dense< ValueType >::create\_submatrix().

The documentation for this class was generated from the following file:

• ginkgo/core/base/array.hpp (8045ac753)

# 26.4 gko::matrix::Hybrid< ValueType, IndexType >::automatic Class Reference

automatic is a stratgy\_type which decides the number of stored elements per row of the ell part automatically. #include <ginkgo/core/matrix/hybrid.hpp>

#### **Public Member Functions**

• automatic ()

Creates an automatic strategy.

• size\_type compute\_ell\_num\_stored\_elements\_per\_row (Array< size\_type > \*row\_nnz) const override

Computes the number of stored elements per row of the ell part.

#### 26.4.1 Detailed Description

```
template < typename ValueType = default_precision, typename IndexType = int32 > class gko::matrix::Hybrid < ValueType, IndexType > ::automatic
```

automatic is a stratgy\_type which decides the number of stored elements per row of the ell part automatically.

#### 26.4.2 Member Function Documentation

#### 26.4.2.1 compute\_ell\_num\_stored\_elements\_per\_row()

Computes the number of stored elements per row of the ell part.

#### **Parameters**

row_nnz	the number of nonzeros of each row
---------	------------------------------------

#### Returns

the number of stored elements per row of the ell part

Implements gko::matrix::Hybrid< ValueType, IndexType >::strategy\_type.

References gko::matrix::Hybrid< ValueType, IndexType >::imbalance\_bounded\_limit::compute\_ell\_num\_stored ← \_\_elements\_per\_row().

The documentation for this class was generated from the following file:

ginkgo/core/matrix/hybrid.hpp (4b82e692f)

## 26.5 gko::BadDimension Class Reference

BadDimension is thrown if an operation is being applied to a LinOp with bad dimensions.

```
#include <ginkgo/core/base/exception.hpp>
```

#### **Public Member Functions**

• BadDimension (const std::string &file, int line, const std::string &func, const std::string &op\_name, size\_type op\_num\_rows, size\_type op\_num\_cols, const std::string &clarification)

Initializes a bad dimension error.

#### 26.5.1 Detailed Description

BadDimension is thrown if an operation is being applied to a LinOp with bad dimensions.

#### 26.5.2 Constructor & Destructor Documentation

#### 26.5.2.1 BadDimension()

Initializes a bad dimension error.

#### **Parameters**

file	The name of the offending source file
line	The source code line number where the error occurred
func	The function name where the error occurred
op_name	The name of the operator
op_num_rows	The row dimension of the operator
op_num_cols	The column dimension of the operator
clarification	An additional message further describing the error

The documentation for this class was generated from the following file:

• ginkgo/core/base/exception.hpp (6e8865457)

## 26.6 gko::solver::Bicgstab< ValueType > Class Template Reference

BiCGSTAB or the Bi-Conjugate Gradient-Stabilized is a Krylov subspace solver.

```
#include <ginkgo/core/solver/bicgstab.hpp>
```

#### **Public Member Functions**

std::shared\_ptr< const LinOp > get\_system\_matrix () const
 Gets the system operator (matrix) of the linear system.

#### 26.6.1 Detailed Description

```
template<typename ValueType = default_precision> class gko::solver::Bicgstab< ValueType >
```

BiCGSTAB or the Bi-Conjugate Gradient-Stabilized is a Krylov subspace solver.

Being a generic solver, it is capable of solving general matrices, including non-s.p.d matrices. Though, the memory and the computational requirement of the BiCGSTAB solver are higher than of its s.p.d solver counterpart, it has the capability to solve generic systems. It was developed by stabilizing the BiCG method.

#### **Template Parameters**

```
ValueType precision of the elements of the system matrix.
```

#### 26.6.2 Member Function Documentation

#### 26.6.2.1 get\_system\_matrix()

```
template<typename ValueType = default_precision>
std::shared_ptr<const LinOp> gko::solver::Bicgstab< ValueType >::get_system_matrix ( ) const
[inline]
```

Gets the system operator (matrix) of the linear system.

#### Returns

```
the system operator (matrix)
```

The documentation for this class was generated from the following file:

• ginkgo/core/solver/bicgstab.hpp (4d55c5d34)

#### 

Defines the parameters of the interleaved block storage scheme used by block-Jacobi blocks.

```
#include <ginkgo/core/preconditioner/jacobi.hpp>
```

#### **Public Member Functions**

• IndexType get\_group\_size () const noexcept

Returns the number of elements in the group.

• size\_type compute\_storage\_space (size\_type num\_blocks) const noexcept

Computes the storage space required for the requested number of blocks.

• IndexType get\_group\_offset (IndexType block\_id) const noexcept

Returns the offset of the group belonging to the block with the given ID.

• IndexType get\_block\_offset (IndexType block\_id) const noexcept

Returns the offset of the block with the given ID within its group.

IndexType get\_global\_block\_offset (IndexType block\_id) const noexcept

Returns the offset of the block with the given ID.

• IndexType get\_stride () const noexcept

Returns the stride between columns of the block.

#### **Public Attributes**

IndexType block\_offset

The offset between consecutive blocks within the group.

IndexType group\_offset

The offset between two block groups.

uint32 group\_power

Then base 2 power of the group.

### 26.7.1 Detailed Description

```
template<typename IndexType> struct gko::preconditioner::block_interleaved_storage_scheme< IndexType >
```

Defines the parameters of the interleaved block storage scheme used by block-Jacobi blocks.

**Template Parameters** 

```
IndexType | type used for storing indices of the matrix
```

#### 26.7.2 Member Function Documentation

#### 26.7.2.1 compute\_storage\_space()

Computes the storage space required for the requested number of blocks.

#### **Parameters**

num_blocks	the total number of blocks that needs to be stored
------------	--

#### Returns

the total memory (as the number of elements) that need to be allocated for the scheme

#### Note

To simplify using the method in situations where the number of blocks is not known, for a special input  $size \leftarrow \_type\{\} - 1$  the method returns 0 to avoid overallocation of memory.

#### 26.7.2.2 get\_block\_offset()

Returns the offset of the block with the given ID within its group.

#### **Parameters**

block⊷	the ID of the block
_id	

#### Returns

the offset of the block with ID block\_id within its group

Referenced by gko::preconditioner::block\_interleaved\_storage\_scheme < index\_type >::get\_global\_block\_offset().

#### 26.7.2.3 get\_global\_block\_offset()

Returns the offset of the block with the given ID.

#### **Parameters**

block⊷	the ID of the block
_id	

#### Returns

the offset of the block with ID block\_id

#### 26.7.2.4 get group offset()

Returns the offset of the group belonging to the block with the given ID.

#### **Parameters**

block←	the ID of the block
_id	

#### Returns

the offset of the group belonging to block with ID block\_id

Referenced by gko::preconditioner::block\_interleaved\_storage\_scheme < index\_type >::get\_global\_block\_offset().

## 26.7.2.5 get\_group\_size()

```
template<typename IndexType>
IndexType gko::preconditioner::block_interleaved_storage_scheme< IndexType >::get_group_size (
) const [inline], [noexcept]
```

Returns the number of elements in the group.

#### Returns

the number of elements in the group

Referenced by gko::preconditioner::block\_interleaved\_storage\_scheme< index\_type >::compute\_storage\_ space(), and gko::preconditioner::block interleaved storage scheme< index\_type >::get\_block offset().

#### 26.7.2.6 get\_stride()

```
template<typename IndexType>
IndexType gko::preconditioner::block_interleaved_storage_scheme< IndexType >::get_stride ( )
const [inline], [noexcept]
```

Returns the stride between columns of the block.

Returns

stride between columns of the block

#### 26.7.3 Member Data Documentation

#### 26.7.3.1 group\_power

```
template<typename IndexType>
uint32 gko::preconditioner::block_interleaved_storage_scheme< IndexType >::group_power
```

Then base 2 power of the group.

I.e. the group contains 1 << group\_power elements.

Referenced by gko::preconditioner::block\_interleaved\_storage\_scheme < index\_type >::get\_group\_offset(), gko  $\leftarrow$  ::preconditioner::block\_interleaved\_storage\_scheme < index\_type >::get\_group\_size(), and gko::preconditioner  $\leftarrow$  ::block\_interleaved\_storage\_scheme < index\_type >::get\_stride().

The documentation for this struct was generated from the following file:

• ginkgo/core/preconditioner/jacobi.hpp (638db8ca9)

## 26.8 gko::solver::Cg< ValueType > Class Template Reference

CG or the conjugate gradient method is an iterative type Krylov subspace method which is suitable for symmetric positive definite methods.

```
#include <ginkgo/core/solver/cg.hpp>
```

#### **Public Member Functions**

std::shared\_ptr< const LinOp > get\_system\_matrix () const
 Gets the system operator (matrix) of the linear system.

#### 26.8.1 Detailed Description

```
\label{template} \begin{tabular}{ll} template < typename \ ValueType = default\_precision > \\ class \ gko::solver::Cg < ValueType > \\ \end{tabular}
```

CG or the conjugate gradient method is an iterative type Krylov subspace method which is suitable for symmetric positive definite methods.

Though this method performs very well for symmetric positive definite matrices, it is in general not suitable for general matrices.

The implementation in Ginkgo makes use of the merged kernel to make the best use of data locality. The inner operations in one iteration of CG are merged into 2 separate steps.

#### **Template Parameters**

ValueType	precision of matrix elements
-----------	------------------------------

#### 26.8.2 Member Function Documentation

#### 26.8.2.1 get\_system\_matrix()

```
template<typename ValueType = default_precision>
std::shared_ptr<const LinOp> gko::solver::Cg< ValueType >::get_system_matrix ( ) const [inline]
```

Gets the system operator (matrix) of the linear system.

#### Returns

the system operator (matrix)

The documentation for this class was generated from the following file:

ginkgo/core/solver/cg.hpp (4d55c5d34)

## 26.9 gko::solver::Cgs< ValueType > Class Template Reference

CGS or the conjugate gradient square method is an iterative type Krylov subspace method which is suitable for general systems.

```
#include <ginkgo/core/solver/cgs.hpp>
```

#### **Public Member Functions**

std::shared\_ptr< const LinOp > get\_system\_matrix () const
 Gets the system operator (matrix) of the linear system.

#### 26.9.1 Detailed Description

```
template<typename ValueType = default_precision> class gko::solver::Cgs< ValueType >
```

CGS or the conjugate gradient square method is an iterative type Krylov subspace method which is suitable for general systems.

The implementation in Ginkgo makes use of the merged kernel to make the best use of data locality. The inner operations in one iteration of CGS are merged into 3 separate steps.

#### **Template Parameters**

ValueType	precision of matrix elements
-----------	------------------------------

#### 26.9.2 Member Function Documentation

#### 26.9.2.1 get\_system\_matrix()

```
template<typename ValueType = default_precision>
std::shared_ptr<const LinOp> gko::solver::Cgs< ValueType >::get_system_matrix ( ) const [inline]
```

Gets the system operator (matrix) of the linear system.

#### Returns

```
the system operator (matrix)
```

```
82 {
83     return system_matrix_;
84 }
```

# 26.10 gko::matrix::Hybrid< ValueType, IndexType >::column\_limit Class Reference

column\_limit is a strategy\_type which decides the number of stored elements per row of the ell part by specifying the number of columns.

```
#include <ginkgo/core/matrix/hybrid.hpp>
```

#### **Public Member Functions**

- column\_limit (size\_type num\_column=0)
   Creates a column\_limit strategy.
- size\_type compute\_ell\_num\_stored\_elements\_per\_row (Array< size\_type > \*row\_nnz) const override

  Computes the number of stored elements per row of the ell part.

#### 26.10.1 Detailed Description

template<typename ValueType = default\_precision, typename IndexType = int32> class gko::matrix::Hybrid< ValueType, IndexType >::column\_limit

column\_limit is a strategy\_type which decides the number of stored elements per row of the ell part by specifying the number of columns.

#### 26.10.2 Constructor & Destructor Documentation

#### 26.10.2.1 column\_limit()

Creates a column limit strategy.

#### **Parameters**

	num_column	the specified number of columns of the ell part
--	------------	---

#### 26.10.3 Member Function Documentation

#### 26.10.3.1 compute\_ell\_num\_stored\_elements\_per\_row()

Computes the number of stored elements per row of the ell part.

#### **Parameters**

row_nnz	the number of nonzeros of each row

#### Returns

the number of stored elements per row of the ell part

Implements gko::matrix::Hybrid< ValueType, IndexType >::strategy\_type.

The documentation for this class was generated from the following file:

ginkgo/core/matrix/hybrid.hpp (4b82e692f)

## 26.11 gko::Combination< ValueType > Class Template Reference

```
The Combination class can be used to construct a linear combination of multiple linear operators c1 * op1 + c2 * op2 + ...
#include <ginkgo/core/base/combination.hpp>
```

#### **Public Member Functions**

- const std::vector< std::shared\_ptr< const LinOp > > & get\_coefficients () const noexcept
   Returns a list of coefficients of the combination.
- const std::vector< std::shared\_ptr< const LinOp >> & get\_operators () const noexcept Returns a list of operators of the combination.

## 26.11.1 Detailed Description

```
template<typename ValueType = default_precision> class gko::Combination< ValueType>
```

The Combination class can be used to construct a linear combination of multiple linear operators c1 \* op1 + c2 \* op2 + ...

• ck \* opk.

#### **Template Parameters**

#### 26.11.2 Member Function Documentation

#### 26.11.2.1 get\_coefficients()

```
template<typename ValueType = default_precision>
const std::vector<std::shared_ptr<const LinOp> >& gko::Combination< ValueType >::get_\(\cup \)
coefficients ( ) const [inline], [noexcept]
```

Returns a list of coefficients of the combination.

#### Returns

#### a list of coefficients

```
70 {
71 return coefficients_;
72 }
```

#### 26.11.2.2 get\_operators()

```
template<typename ValueType = default_precision>
const std::vector<std::shared_ptr<const LinOp> >& gko::Combination< ValueType >::get_
operators ( ) const [inline], [noexcept]
```

Returns a list of operators of the combination.

#### Returns

a list of operators

The documentation for this class was generated from the following file:

ginkgo/core/base/combination.hpp (b6e1321a0)

# 26.12 gko::stop::Combined Class Reference

The Combined class is used to combine multiple criterions together through an OR operation.

```
#include <ginkgo/core/stop/combined.hpp>
```

# 26.12.1 Detailed Description

The Combined class is used to combine multiple criterions together through an OR operation.

The typical use case is to stop the iteration process if any of the criteria is fulfilled, e.g. a number of iterations, the relative residual norm has reached a threshold, etc.

The documentation for this class was generated from the following file:

• ginkgo/core/stop/combined.hpp (638db8ca9)

# 26.13 gko::Composition < ValueType > Class Template Reference

```
The Composition class can be used to compose linear operators op1, op2, ..., opn and obtain the operator op1 * op2 * ... \#include < ginkgo/core/base/composition.hpp>
```

# **Public Member Functions**

const std::vector< std::shared\_ptr< const LinOp >> & get\_operators () const noexcept
 Returns a list of operators of the composition.

# 26.13.1 Detailed Description

```
\label{template} $$ \ensuremath{\mathsf{template}}$ - \ensuremath{\mathsf{valueType}} = \ensuremath{\mathsf{default\_precision}} > \\ \ensuremath{\mathsf{class}} \ensuremath{\mathsf{gko}} :: \ensuremath{\mathsf{Composition}} < \ensuremath{\mathsf{ValueType}} > \\ \ensuremath{\mathsf{valueType}}
```

The Composition class can be used to compose linear operators op1, op2, ..., opn and obtain the operator op1 \* op2 \* ...

· opn.

# **Template Parameters**

ValueType	precision of input and result vectors
-----------	---------------------------------------

### 26.13.2 Member Function Documentation

#### 26.13.2.1 get\_operators()

```
template<typename ValueType = default_precision>
const std::vector<std::shared_ptr<const LinOp> >& gko::Composition< ValueType >::get_
operators ( ) const [inline], [noexcept]
```

Returns a list of operators of the composition.

#### Returns

#### a list of operators

The documentation for this class was generated from the following file:

ginkgo/core/base/composition.hpp (b6e1321a0)

# 26.14 gko::log::Convergence< ValueType > Class Template Reference

Convergence is a Logger which logs data strictly from the criterion\_check\_completed event.

```
#include <ginkgo/core/log/convergence.hpp>
```

#### **Public Member Functions**

• const size\_type & get\_num\_iterations () const noexcept

Returns the number of iterations.

const LinOp \* get\_residual () const noexcept

Returns the residual.

• const LinOp \* get\_residual\_norm () const noexcept

Returns the residual norm.

# **Static Public Member Functions**

Creates a convergence logger.

# 26.14.1 Detailed Description

```
template<typename ValueType = default_precision> class gko::log::Convergence< ValueType >
```

Convergence is a Logger which logs data strictly from the criterion\_check\_completed event.

The purpose of this logger is to give a simple access to standard data generated by the solver once it has converged with minimal overhead.

This logger also computes the residual norm from the residual when the residual norm was not available. This can add some slight overhead.

# 26.14.2 Member Function Documentation

#### 26.14.2.1 create()

Creates a convergence logger.

This dynamically allocates the memory, constructs the object and returns an std::unique\_ptr to this object.

#### **Parameters**

exec	the executor
enabled_events	the events enabled for this logger. By default all events.

# Returns

an std::unique\_ptr to the the constructed object

#### 26.14.2.2 get\_num\_iterations()

```
template<typename ValueType = default_precision>
const size_type& gko::log::Convergence< ValueType >::get_num_iterations ( ) const [inline],
[noexcept]
```

Returns the number of iterations.

#### Returns

the number of iterations

#### 26.14.2.3 get\_residual()

```
template<typename ValueType = default_precision>
const LinOp* gko::log::Convergence< ValueType >::get_residual ( ) const [inline], [noexcept]
```

Returns the residual.

#### Returns

the residual

#### 26.14.2.4 get\_residual\_norm()

```
template<typename ValueType = default_precision>
const LinOp* gko::log::Convergence< ValueType >::get_residual_norm ( ) const [inline], [noexcept]
```

Returns the residual norm.

#### Returns

the residual norm

The documentation for this class was generated from the following file:

• ginkgo/core/log/convergence.hpp (f1a4eb68b)

# 26.15 gko::ConvertibleTo< ResultType > Class Template Reference

ConvertibleTo interface is used to mark that the implementer can be converted to the object of ResultType.

```
#include <ginkgo/core/base/polymorphic_object.hpp>
```

#### **Public Member Functions**

- virtual void convert\_to (result\_type \*result) const =0
   Converts the implementer to an object of type result\_type.
- virtual void move\_to (result\_type \*result)=0

Converts the implementer to an object of type result\_type by moving data from this object.

# 26.15.1 Detailed Description

```
template<typename ResultType> class gko::ConvertibleTo< ResultType >
```

ConvertibleTo interface is used to mark that the implementer can be converted to the object of ResultType.

This interface is used to enable conversions between polymorphic objects. To mark that an object of type U can be converted to an object of type V, U should implement ConvertibleTo<V>. Then, the implementation of PolymorphicObject::copy\_from automatically generated by EnablePolymorphicObject mixin will use RTTI to figure out that U implements the interface and convert it using the convert\_to / move\_to methods of the interface.

#### As an example, the following function:

```
{c++}
void my_function(const U *u, V *v) {
   v->copy_from(u);
}
```

will convert object u to object v by checking that u can be dynamically casted to ConvertibleTo<V>, and calling ConvertibleTo<V>::convert\_to(V\*)` to do the actual conversion.

In case u is passed as a unique\_ptr, call to  $convert\_to$  will be replaced by a call to  $move\_to$  and trigger move semantics.

# **Template Parameters**

ResultType the type to which the implementer can be converted to, has to be a subclass of PolymorphicObject

#### 26.15.2 Member Function Documentation

#### 26.15.2.1 convert to()

Converts the implementer to an object of type result\_type.

#### **Parameters**

result the object used to store the result of the conversion

Implemented in gko::EnablePolymorphicAssignment < ConcreteType, ResultType >, gko::EnablePolymorphicAssignment < SparsityOgko::EnablePolymorphicAssignment < Dense < ValueType > >, gko::EnablePolymorphicAssignment < UpperTrs < ValueType, IndexType : gko::EnablePolymorphicAssignment < Hybrid < ValueType, IndexType > >, gko::EnablePolymorphicAssignment < Identity < ValueTygko::EnablePolymorphicAssignment < ConcreteLinOp >, gko::EnablePolymorphicAssignment < Composition < ValueType > >, gko::EnablePolymorphicAssignment < LowerTrs < ValueType, IndexType : gko::EnablePolymorphicAssignment < Combination < ValueType > >, gko::EnablePolymorphicAssignment < Combination < ValueType > >, gko::EnablePolymorphicAssignment < Gmres < ValueType > >

 $\label{thm:condition} gko::EnablePolymorphicAssignment < Csr < ValueType, IndexType >>, gko::EnablePolymorphicAssignment < Ir < ValueType >>, gko::EnablePolymorphicAssignment < Ir < ValueType >>, gko::EnablePolymorphicAssignment < Fcg < ValueType >> gko::EnablePolymorphicAssignment < Ilu < LSolverType, USolverType, ReverseApply >>, gko::EnablePolymorphicAssignment < Cg < ValueType, IndexType >> gko::EnablePolymorphicAssignment < Ell < ValueType, IndexType >> gko::EnablePolymorphicAssignment < Cg < ValueType, IndexType >>, gko::EnablePolymorphicAssignment < Cg < ValueType >> gko::EnablePolymorphicAssignment < Cg < ValueType >> gko::EnablePolymorphicAssignment < Perturbation < ValueType, IndexType >> , gko::EnablePolymorphicAssignment < Perturb$ 

#### 26.15.2.2 move to()

Converts the implementer to an object of type result type by moving data from this object.

This method is used when the implementer is a temporary object, and move semantics can be used.

#### **Parameters**

result   the object used to emplace the result of the conversion
--

#### Note

ConvertibleTo::move\_to can be implemented by simply calling ConvertibleTo::convert\_to. However, this operation can often be optimized by exploiting the fact that implementer's data can be moved to the result.

# 26.16 gko::matrix::Coo< ValueType, IndexType > Class Template Reference

COO stores a matrix in the coordinate matrix format.

#include <ginkgo/core/matrix/coo.hpp>

#### **Public Member Functions**

void read (const mat\_data &data) override

Reads a matrix from a matrix\_data structure.

· void write (mat\_data &data) const override

Writes a matrix to a matrix\_data structure.

value\_type \* get\_values () noexcept

Returns the values of the matrix.

const value\_type \* get\_const\_values () const noexcept

Returns the values of the matrix.

index\_type \* get\_col\_idxs () noexcept

Returns the column indexes of the matrix.

• const index\_type \* get\_const\_col\_idxs () const noexcept

Returns the column indexes of the matrix.

index\_type \* get\_row\_idxs () noexcept

Returns the row indexes of the matrix.

- const index\_type \* get\_const\_row\_idxs () const noexcept
- size\_type get\_num\_stored\_elements () const noexcept

Returns the number of elements explicitly stored in the matrix.

LinOp \* apply2 (const LinOp \*b, LinOp \*x)

Applies Coo matrix axpy to a vector (or a sequence of vectors).

- const LinOp \* apply2 (const LinOp \*b, LinOp \*x) const
- LinOp \* apply2 (const LinOp \*alpha, const LinOp \*b, LinOp \*x)

Performs the operation x = alpha \* Coo \* b + x.

• const LinOp \* apply2 (const LinOp \*alpha, const LinOp \*b, LinOp \*x) const

Performs the operation x = alpha \* Coo \* b + x.

# 26.16.1 Detailed Description

template<typename ValueType = default\_precision, typename IndexType = int32> class gko::matrix::Coo< ValueType, IndexType >

COO stores a matrix in the coordinate matrix format.

The nonzero elements are stored in an array row-wise (but not neccessarily sorted by column index within a row). Two extra arrays contain the row and column indexes of each nonzero element of the matrix.

### **Template Parameters**

ValueType	precision of matrix elements
IndexType	precision of matrix indexes

# 26.16.2 Member Function Documentation

# 26.16.2.1 apply2() [1/4]

Performs the operation x = alpha \* Coo \* b + x.

#### **Parameters**

alpha	scaling of the result of Coo * b
b	vector(s) on which the operator is applied
X	output vector(s)

#### Returns

```
this
```

References gko::PolymorphicObject::get\_executor(), and gko::make\_temporary\_clone().

# 26.16.2.2 apply2() [2/4]

Performs the operation x = alpha \* Coo \* b + x.

#### **Parameters**

alpha	scaling of the result of Coo * b
b	vector(s) on which the operator is applied
X	output vector(s)

#### Returns

this

References gko::PolymorphicObject::get\_executor(), and gko::make\_temporary\_clone().

#### 26.16.2.3 apply2() [3/4]

Applies Coo matrix axpy to a vector (or a sequence of vectors).

Performs the operation x = Coo \* b + x

#### **Parameters**

	the input vector(s) on which the operator is applied
X	the output vector(s) where the result is stored

#### Returns

this

References gko::PolymorphicObject::get executor(), and gko::make temporary clone().

```

Returns the row indexes of the matrix.

#### Returns

the row indexes of the matrix.

References gko::Array< ValueType >::get\_data().

# 26.16.2.11 get\_values()

```
template<typename ValueType = default_precision, typename IndexType = int32>
value_type* gko::matrix::Coo< ValueType, IndexType >::get_values () [inline], [noexcept]
```

Returns the values of the matrix.

#### Returns

the values of the matrix.

References gko::Array< ValueType >::get\_data().

#### 26.16.2.12 read()

Reads a matrix from a matrix\_data structure.

#### **Parameters**

```
data the matrix_data structure
```

Implements gko::ReadableFromMatrixData< ValueType, IndexType >.

#### 26.16.2.13 write()

Writes a matrix to a matrix\_data structure.

#### **Parameters**

```
data the matrix_data structure
```

Implements gko::WritableToMatrixData< ValueType, IndexType >.

The documentation for this class was generated from the following file:

• ginkgo/core/matrix/coo.hpp (2f671dafa)

# 26.17 gko::copy\_back\_deleter< T > Class Template Reference

A copy\_back\_deleter is a type of deleter that copies the data to an internally referenced object before performing the deletion.

#include <ginkgo/core/base/utils.hpp>

#### **Public Member Functions**

copy\_back\_deleter (pointer original)

Creates a new deleter object.

void operator() (pointer ptr) const

Deletes the object.

# 26.17.1 Detailed Description

```
\label{template} \begin{split} \text{template} &< \text{typename T}> \\ \text{class gko::copy\_back\_deleter} &< \text{T}> \end{split}
```

A copy\_back\_deleter is a type of deleter that copies the data to an internally referenced object before performing the deletion.

The deleter will use the <code>copy\_from</code> method to perform the copy, and then delete the passed object using the <code>delete</code> keyword. This kind of deleter is useful when temporarily copying an object with the intent of copying it back once it goes out of scope.

There is also a specialization for constant objects that does not perform the copy, since a constant object couldn't have been changed.

**Template Parameters** 

T | the type of object being deleted

#### 26.17.2 Constructor & Destructor Documentation

# 26.17.2.1 copy\_back\_deleter()

Creates a new deleter object.

#### **Parameters**

original the origin object where the data will be copied before deletion

# 26.17.3 Member Function Documentation

# 26.17.3.1 operator()()

Deletes the object.

#### **Parameters**

ptr pointer to the object being deleted

The documentation for this class was generated from the following file:

• ginkgo/core/base/utils.hpp (ffa4bb4e4)

# 26.18 gko::stop::Criterion Class Reference

The Criterion class is a base class for all stopping criteria.

#include <ginkgo/core/stop/criterion.hpp>

#### **Classes**

· class Updater

The Updater class serves for convenient argument passing to the Criterion's check function.

# **Public Member Functions**

• Updater update ()

Returns the updater object.

bool check (uint8 stoppingId, bool setFinalized, Array< stopping\_status > \*stop\_status, bool \*one\_changed, const Updater &updater)

This checks whether convergence was reached for a certain criterion.

# 26.18.1 Detailed Description

The Criterion class is a base class for all stopping criteria.

It contains a factory to instantiate criteria. It is up to each specific stopping criterion to decide what to do with the data that is passed to it.

Note that depending on the criterion, convergence may not have happened after stopping.

#### 26.18.2 Member Function Documentation

# 26.18.2.1 check()

```
bool gko::stop::Criterion::check (
          uint8 stoppingId,
          bool setFinalized,
          Array< stopping_status > * stop_status,
          bool * one_changed,
          const Updater & updater ) [inline]
```

This checks whether convergence was reached for a certain criterion.

The actual implantation of the criterion goes here.

#### **Parameters**

stoppingld	id of the stopping criterion
setFinalized	Controls if the current version should count as finalized or not
stop_status	status of the stopping criterion
one_changed	indicates if one vector's status changed
updater	the Updater object containing all the information

Returns

whether convergence was completely reached

```
152
153
           this->template log<log::Logger::criterion_check_started>(
154
               this, updater.num_iterations_, updater.residual_,
155
               updater.residual_norm_, updater.solution_, stoppingId,
156
               setFinalized);
           auto all_converged = this->check_impl(
157
158
               stoppingId, setFinalized, stop_status, one_changed, updater);
           this->template log<log::Logger::criterion_check_completed>(
               this, updater.num_iterations_, updater.residual_
161
               updater.residual_norm_, updater.solution_, stoppingId, setFinalized,
162
               stop_status, *one_changed, all_converged);
163
           return all_converged;
164
```

Referenced by gko::stop::Criterion::Updater::check().

#### 26.18.2.2 update()

```
Updater gko::stop::Criterion::update ( ) [inline]
```

Returns the updater object.

Returns

the updater object

The documentation for this class was generated from the following file:

• ginkgo/core/stop/criterion.hpp (da7880906)

# 26.19 gko::log::criterion\_data Struct Reference

Struct representing Criterion related data.

```
#include <ginkgo/core/log/record.hpp>
```

# 26.19.1 Detailed Description

Struct representing Criterion related data.

The documentation for this struct was generated from the following file:

ginkgo/core/log/record.hpp (f0a50f96f)

# 26.20 gko::stop::CriterionArgs Struct Reference

This struct is used to pass parameters to the EnableDefaultCriterionFactoryCriterionFactory::generate() method.

```
#include <ginkgo/core/stop/criterion.hpp>
```

# 26.20.1 Detailed Description

This struct is used to pass parameters to the EnableDefaultCriterionFactoryCriterionFactory::generate() method.

It is the ComponentsType of CriterionFactory.

Note

Dependly on the use case, some of these parameters can be nullptr as only some stopping criterion require them to be set. An example is the ResidualNormReduction which really requires the initial — residual to be set.

The documentation for this struct was generated from the following file:

• ginkgo/core/stop/criterion.hpp (da7880906)

# 26.21 gko::matrix::Csr< ValueType, IndexType > Class Template Reference

CSR is a matrix format which stores only the nonzero coefficients by compressing each row of the matrix (compressed sparse row format).

#include <ginkgo/core/matrix/csr.hpp>

#### **Public Member Functions**

· void read (const mat\_data &data) override

Reads a matrix from a matrix\_data structure.

void write (mat\_data &data) const override

Writes a matrix to a matrix\_data structure.

• std::unique\_ptr< LinOp > transpose () const override

Returns a LinOp representing the transpose of the Transposable object.

std::unique\_ptr< LinOp > conj\_transpose () const override

Returns a LinOp representing the conjugate transpose of the Transposable object.

void sort\_by\_column\_index ()

Sorts all (value, col\_idx) pairs in each row by column index.

value\_type \* get\_values () noexcept

Returns the values of the matrix.

const value\_type \* get\_const\_values () const noexcept

Returns the values of the matrix.

index\_type \* get\_col\_idxs () noexcept

Returns the column indexes of the matrix.

• const index\_type \* get\_const\_col\_idxs () const noexcept

Returns the column indexes of the matrix.

index\_type \* get\_row\_ptrs () noexcept

Returns the row pointers of the matrix.

const index type \* get const row ptrs () const noexcept

Returns the row pointers of the matrix.

index\_type \* get\_srow () noexcept

Returns the starting rows.

const index\_type \* get\_const\_srow () const noexcept

Returns the starting rows.

size\_type get\_num\_srow\_elements () const noexcept

Returns the number of the srow stored elements (involved warps)

• size\_type get\_num\_stored\_elements () const noexcept

Returns the number of elements explicitly stored in the matrix.

std::shared\_ptr< strategy\_type > get\_strategy () const noexcept
 Returns the strategy.

# 26.21.1 Detailed Description

```
template < typename ValueType = default_precision, typename IndexType = int32 > class gko::matrix::Csr < ValueType, IndexType >
```

CSR is a matrix format which stores only the nonzero coefficients by compressing each row of the matrix (compressed sparse row format).

The nonzero elements are stored in a 1D array row-wise, and accompanied with a row pointer array which stores the starting index of each row. An additional column index array is used to identify the column of each nonzero element.

#### **Template Parameters**

ValueType	precision of matrix elements
IndexType	precision of matrix indexes

#### 26.21.2 Member Function Documentation

# 26.21.2.1 conj\_transpose()

```
template<typename ValueType = default_precision, typename IndexType = int32>
std::unique_ptr<LinOp> gko::matrix::Csr< ValueType, IndexType >::conj_transpose ( ) const
[override], [virtual]
```

Returns a LinOp representing the conjugate transpose of the Transposable object.

### Returns

a pointer to the new conjugate transposed object

Implements gko::Transposable.

#### 26.21.2.2 get\_col\_idxs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
index_type* gko::matrix::Csr< ValueType, IndexType >::get_col_idxs ( ) [inline], [noexcept]
```

Returns the column indexes of the matrix.

#### Returns

the column indexes of the matrix.

```
392 { return col_idxs_.get_data(); }
```

References gko::Array< ValueType >::get\_data().

#### 26.21.2.3 get const col idxs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const index_type* gko::matrix::Csr< ValueType, IndexType >::get_const_col_idxs ( ) const [inline],
[noexcept]
```

Returns the column indexes of the matrix.

#### Returns

the column indexes of the matrix.

#### Note

This is the constant version of the function, which can be significantly more memory efficient than the non-constant version, so always prefer this version.

References gko::Array< ValueType >::get\_const\_data().

# 26.21.2.4 get\_const\_row\_ptrs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const index_type* gko::matrix::Csr< ValueType, IndexType >::get_const_row_ptrs ( ) const [inline],
[noexcept]
```

Returns the row pointers of the matrix.

#### Returns

the row pointers of the matrix.

#### Note

This is the constant version of the function, which can be significantly more memory efficient than the non-constant version, so always prefer this version.

References gko::Array< ValueType >::get\_const\_data().

#### 26.21.2.5 get\_const\_srow()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const index_type* gko::matrix::Csr< ValueType, IndexType >::get_const_srow ( ) const [inline],
[noexcept]
```

Returns the starting rows.

#### Returns

the starting rows.

#### Note

This is the constant version of the function, which can be significantly more memory efficient than the non-constant version, so always prefer this version.

References gko::Array < ValueType >::get\_const\_data().

#### 26.21.2.6 get const values()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const value_type* gko::matrix::Csr< ValueType, IndexType >::get_const_values ( ) const [inline],
[noexcept]
```

Returns the values of the matrix.

#### Returns

the values of the matrix.

#### Note

This is the constant version of the function, which can be significantly more memory efficient than the non-constant version, so always prefer this version.

size_type gko::matrix::Csr< ValueType, IndexType >::get_num_srow_elements ( ) const [inline],
[noexcept]
```

Returns the number of the srow stored elements (involved warps)

#### Returns

the number of the srow stored elements (involved warps)

References gko::Array< ValueType >::get\_num\_elems().

#### 26.21.2.8 get\_num\_stored\_elements()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::Csr< ValueType, IndexType >::get_num_stored_elements ( ) const [inline],
[noexcept]
```

Returns the number of elements explicitly stored in the matrix.

#### Returns

the number of elements explicitly stored in the matrix

References gko::Array < ValueType >::get\_num\_elems().

#### 26.21.2.9 get\_row\_ptrs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
index_type* gko::matrix::Csr< ValueType, IndexType >::get_row_ptrs ( ) [inline], [noexcept]
```

Returns the row pointers of the matrix.

#### Returns

the row pointers of the matrix.

References gko::Array< ValueType >::get\_data().

#### 26.21.2.10 get\_srow()

```
template<typename ValueType = default_precision, typename IndexType = int32>
index_type* gko::matrix::Csr< ValueType, IndexType >::get_srow () [inline], [noexcept]
```

Returns the starting rows.

# Returns

the starting rows.

References gko::Array< ValueType >::get data().

#### 26.21.2.11 get\_strategy()

```
template<typename ValueType = default_precision, typename IndexType = int32>
std::shared_ptr<strategy_type> gko::matrix::Csr< ValueType, IndexType >::get_strategy ( )
const [inline], [noexcept]
```

Returns the strategy.

Returns

the strategy

#### 26.21.2.12 get\_values()

```
template<typename ValueType = default_precision, typename IndexType = int32>
value_type* gko::matrix::Csr< ValueType, IndexType >::get_values () [inline], [noexcept]
```

Returns the values of the matrix.

Returns

the values of the matrix.

References gko::Array< ValueType >::get data().

## 26.21.2.13 read()

Reads a matrix from a matrix data structure.

**Parameters** 

```
data the matrix_data structure
```

Implements gko::ReadableFromMatrixData< ValueType, IndexType >.

# 26.21.2.14 transpose()

```
template<typename ValueType = default_precision, typename IndexType = int32>
std::unique_ptr<LinOp> gko::matrix::Csr< ValueType, IndexType >::transpose ( ) const [override],
[virtual]
```

Returns a LinOp representing the transpose of the Transposable object.

#### Returns

a pointer to the new transposed object

Implements gko::Transposable.

# 26.21.2.15 write()

Writes a matrix to a matrix\_data structure.

#### **Parameters**

```
data the matrix_data structure
```

Implements gko::WritableToMatrixData< ValueType, IndexType >.

The documentation for this class was generated from the following files:

# 26.22 gko::CublasError Class Reference

CublasError is thrown when a cuBLAS routine throws a non-zero error code.

```
#include <ginkgo/core/base/exception.hpp>
```

# **Public Member Functions**

CublasError (const std::string &file, int line, const std::string &func, int64 error\_code)
 Initializes a cuBLAS error.

# 26.22.1 Detailed Description

CublasError is thrown when a cuBLAS routine throws a non-zero error code.

## 26.22.2 Constructor & Destructor Documentation

#### 26.22.2.1 CublasError()

Initializes a cuBLAS error.

#### **Parameters**

file	The name of the offending source file
line	The source code line number where the error occurred
func	The name of the cuBLAS routine that failed
error_code	The resulting cuBLAS error code

The documentation for this class was generated from the following file:

ginkgo/core/base/exception.hpp (6e8865457)

# 26.23 gko::CudaError Class Reference

CudaError is thrown when a CUDA routine throws a non-zero error code.

```
#include <ginkgo/core/base/exception.hpp>
```

# **Public Member Functions**

CudaError (const std::string &file, int line, const std::string &func, int64 error\_code)
 Initializes a CUDA error.

# 26.23.1 Detailed Description

CudaError is thrown when a CUDA routine throws a non-zero error code.

# 26.23.2 Constructor & Destructor Documentation

#### 26.23.2.1 CudaError()

Initializes a CUDA error.

#### **Parameters**

file	The name of the offending source file
line	The source code line number where the error occurred
func	The name of the CUDA routine that failed
error_code	The resulting CUDA error code

The documentation for this class was generated from the following file:

• ginkgo/core/base/exception.hpp (6e8865457)

# 26.24 gko::CudaExecutor Class Reference

This is the Executor subclass which represents the CUDA device.

#include <ginkgo/core/base/executor.hpp>

#### **Public Member Functions**

- std::shared\_ptr< Executor > get\_master () noexcept override
   Returns the master OmpExecutor of this Executor.
- std::shared\_ptr< const  ${\sf Executor} > {\sf get\_master}$  () const noexcept override
- Returns the master OmpExecutor of this Executor.
- · void synchronize () const override
  - Synchronize the operations launched on the executor with its master.
- void run (const Operation &op) const override
  - Runs the specified Operation using this Executor.
- int get\_device\_id () const noexcept
  - Get the CUDA device id of the device associated to this executor.
- int get\_num\_cores\_per\_sm () const noexcept
  - Get the number of cores per SM of this executor.
- int get\_num\_multiprocessor () const noexcept
  - Get the number of multiprocessor of this executor.
- int get\_num\_warps () const noexcept
  - Get the number of warps of this executor.
- int get\_major\_version () const noexcept
  - Get the major verion of compute capability.
- int get\_minor\_version () const noexcept
  - Get the minor verion of compute capability.
- cublasContext \* get\_cublas\_handle () const
  - Get the cubias handle for this executor.
- cusparseContext \* get\_cusparse\_handle () const
  - Get the cusparse handle for this executor.

# **Static Public Member Functions**

- static std::shared\_ptr< CudaExecutor > create (int device\_id, std::shared\_ptr< Executor > master)
   Creates a new CudaExecutor.
- static int get\_num\_devices ()

Get the number of devices present on the system.

# 26.24.1 Detailed Description

This is the Executor subclass which represents the CUDA device.

#### 26.24.2 Member Function Documentation

# 26.24.2.1 create()

Creates a new CudaExecutor.

#### **Parameters**

device← _id	the CUDA device id of this device
master	an executor on the host that is used to invoke the device kernels

#### 26.24.2.2 get cublas handle()

```
cublasContext* gko::CudaExecutor::get_cublas_handle ( ) const [inline]
```

Get the cublas handle for this executor.

#### Returns

the cublas handle (cublasContext\*) for this executor

```
875 { return cublas_handle_.get(); }
```

# 26.24.2.3 get\_cusparse\_handle()

```
cusparseContext* gko::CudaExecutor::get_cusparse_handle ( ) const [inline]
```

Get the cusparse handle for this executor.

#### Returns

the cusparse handle (cusparseContext\*) for this executor

# 26.24.2.4 get\_master() [1/2]

```
std::shared_ptr<const Executor> gko::CudaExecutor::get_master ( ) const [override], [virtual],
[noexcept]
```

Returns the master OmpExecutor of this Executor.

#### Returns

the master OmpExecutor of this Executor.

Implements gko::Executor.

# 26.24.2.5 get\_master() [2/2]

```
std::shared_ptr<Executor> gko::CudaExecutor::get_master ( ) [override], [virtual], [noexcept]
```

Returns the master OmpExecutor of this Executor.

#### Returns

the master OmpExecutor of this Executor.

Implements gko::Executor.

#### 26.24.2.6 run()

Runs the specified Operation using this Executor.

#### **Parameters**

op the operation to run	
-------------------------	--

Implements gko::Executor.

The documentation for this class was generated from the following file:

• ginkgo/core/base/executor.hpp (8f70a7c81)

# 26.25 gko::CusparseError Class Reference

CusparseError is thrown when a cuSPARSE routine throws a non-zero error code.

```
#include <ginkgo/core/base/exception.hpp>
```

# **Public Member Functions**

• CusparseError (const std::string &file, int line, const std::string &func, int64 error\_code)

Initializes a cuSPARSE error.

# 26.26 gko::default\_converter < S, R > Struct Template Reference

Used to convert objects of type S to objects of type R using static\_cast.

```
#include <ginkgo/core/base/math.hpp>
```

# **Public Member Functions**

R operator() (S val)
 Converts the object to result type.

# 26.26.1 Detailed Description

```
template<typename S, typename R> struct gko::default_converter< S, R >
```

Used to convert objects of type S to objects of type R using static\_cast.

#### **Template Parameters**

S	source type
R	result type

# 26.26.2 Member Function Documentation

# 26.26.2.1 operator()()

Converts the object to result type.

#### **Parameters**

val the object to conv	ert
------------------------	-----

Returns

the converted object

The documentation for this struct was generated from the following file:

ginkgo/core/base/math.hpp (5fa025073)

# 26.27 gko::matrix::Dense< ValueType > Class Template Reference

Dense is a matrix format which explicitly stores all values of the matrix.

#include <ginkgo/core/matrix/dense.hpp>

#### **Public Member Functions**

• std::unique\_ptr< LinOp > transpose () const override

Returns a LinOp representing the transpose of the Transposable object.

• std::unique\_ptr< LinOp > conj\_transpose () const override

Returns a LinOp representing the conjugate transpose of the Transposable object.

value\_type \* get\_values () noexcept

Returns a pointer to the array of values of the matrix.

const value\_type \* get\_const\_values () const noexcept

Returns a pointer to the array of values of the matrix.

size\_type get\_stride () const noexcept

Returns the stride of the matrix.

• size\_type get\_num\_stored\_elements () const noexcept

Returns the number of elements explicitly stored in the matrix.

value\_type & at (size\_type row, size\_type col) noexcept

Returns a single element of the matrix.

value\_type at (size\_type row, size\_type col) const noexcept

Returns a single element of the matrix.

• ValueType & at (size\_type idx) noexcept

Returns a single element of the matrix.

ValueType at (size\_type idx) const noexcept

Returns a single element of the matrix.

void scale (const LinOp \*alpha)

Scales the matrix with a scalar (aka: BLAS scal).

void add\_scaled (const LinOp \*alpha, const LinOp \*b)

Adds b scaled by alpha to the matrix (aka: BLAS axpy).

void compute dot (const LinOp \*b, LinOp \*result) const

Computes the column-wise dot product of this matrix and b.

void compute\_norm2 (LinOp \*result) const

Computes the Euclidian ( $L^{\wedge}$ 2) norm of this matrix.

std::unique\_ptr< Dense > create\_submatrix (const span &rows, const span &columns, const size\_type stride)

Create a submatrix from the original matrix.

# **Static Public Member Functions**

static std::unique\_ptr< Dense > create\_with\_config\_of (const Dense \*other)
 Creates a Dense matrix with the configuration of another Dense matrix.

# 26.27.1 Detailed Description

```
template<typename ValueType = default_precision> class gko::matrix::Dense< ValueType >
```

Dense is a matrix format which explicitly stores all values of the matrix.

The values are stored in row-major format (values belonging to the same row appear consecutive in the memory). Optionally, rows can be padded for better memory access.

#### **Template Parameters**

ValueType precision of matrix elements
--

#### Note

While this format is not very useful for storing sparse matrices, it is often suitable to store vectors, and sets of vectors.

# 26.27.2 Member Function Documentation

# 26.27.2.1 add\_scaled()

Adds b scaled by alpha to the matrix (aka: BLAS axpy).

# **Parameters**

alpha	If alpha is 1x1 Dense matrix, the entire matrix is scaled by alpha. If it is a Dense row vector of values, then i-th column of the matrix is scaled with the i-th element of alpha (the number of columns of alpha has to match the number of columns of the matrix).
b	a matrix of the same dimension as this

References gko::PolymorphicObject::get\_executor(), and gko::make\_temporary\_clone().

#### 26.27.2.2 at() [1/4]

Returns a single element of the matrix.

Useful for iterating across all elements of the matrix. However, it is less efficient than the two-parameter variant of this method.

#### **Parameters**

idx a linear index of the requested element (ignoring the stride)

#### Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the OMP results in a runtime error)

References gko::Array< ValueType >::get\_const\_data().

#### 26.27.2.3 at() [2/4]

Returns a single element of the matrix.

Useful for iterating across all elements of the matrix. However, it is less efficient than the two-parameter variant of this method.

#### **Parameters**

idx a linear index of the requested element (ignoring the stride)

#### Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the OMP results in a runtime error)

References gko::Array< ValueType >::get\_data().

#### 26.27.2.4 at() [3/4]

Returns a single element of the matrix.

#### **Parameters**

	the row of the requested element
col	the column of the requested element

#### Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the OMP results in a runtime error)

References gko::Array< ValueType >::get\_const\_data().

# 26.27.2.5 at() [4/4]

Returns a single element of the matrix.

### **Parameters**

	the row of the requested element
col	the column of the requested element

#### Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the OMP results in a runtime error)

References gko::Array< ValueType >::get\_data().

Referenced by gko::initialize().

#### 26.27.2.6 compute\_dot()

Computes the column-wise dot product of this matrix and b.

The conjugate of this is taken.

#### **Parameters**

b	a Dense matrix of same dimension as this
result	a Dense row vector, used to store the dot product (the number of column in the vector must match the
	number of columns of this)

References gko::PolymorphicObject::get\_executor(), and gko::make\_temporary\_clone().

# 26.27.2.7 compute\_norm2()

Computes the Euclidian ( $L^2$ ) norm of this matrix.

#### **Parameters**

result	a Dense row vector, used to store the norm (the number of columns in the vector must match the
	number of columns of this)

References gko::PolymorphicObject::get\_executor(), and gko::make\_temporary\_clone().

# 26.27.2.8 conj\_transpose()

```
template<typename ValueType = default_precision>
std::unique_ptr<LinOp> gko::matrix::Dense< ValueType >::conj_transpose ( ) const [override],
[virtual]
```

Returns a LinOp representing the conjugate transpose of the Transposable object.

#### Returns

a pointer to the new conjugate transposed object

Implements gko::Transposable.

#### 26.27.2.9 create\_submatrix()

Create a submatrix from the original matrix.

Warning: defining stride for this create\_submatrix method might cause wrong memory access. Better use the create\_submatrix(rows, columns) method instead.

#### **Parameters**

rows	row span
columns	column span
stride	stride of the new submatrix.

References gko::span::begin, gko::PolymorphicObject::get\_executor(), gko::matrix::Dense< ValueType >::get\_
stride(), gko::matrix::Dense< ValueType >::get\_values(), and gko::Array< ValueType >::view().

#### 26.27.2.10 create\_with\_config\_of()

Creates a Dense matrix with the configuration of another Dense matrix.

## **Parameters**

(	other	The other matrix whose configuration needs to copied.
---	-------	---

#### 26.27.2.11 get\_const\_values()

```
template<typename ValueType = default_precision>
const value_type* gko::matrix::Dense< ValueType >::get_const_values ( ) const [inline], [noexcept]
```

Returns a pointer to the array of values of the matrix.

#### Returns

the pointer to the array of values

Note

This is the constant version of the function, which can be significantly more memory efficient than the non-constant version, so always prefer this version.

References gko::Array< ValueType >::get\_const\_data().

#### 26.27.2.12 get\_num\_stored\_elements()

```
template<typename ValueType = default_precision>
size_type gko::matrix::Dense< ValueType >::get_num_stored_elements ( ) const [inline], [noexcept]
```

Returns the number of elements explicitly stored in the matrix.

Returns

the number of elements explicitly stored in the matrix

References gko::Array< ValueType >::get\_num\_elems().

# 26.27.2.13 get\_stride()

```
template<typename ValueType = default_precision>
size_type gko::matrix::Dense< ValueType >::get_stride ( ) const [inline], [noexcept]
```

Returns the stride of the matrix.

Returns

the stride of the matrix.

Referenced by gko::matrix::Dense< ValueType >::create\_submatrix().

#### 26.27.2.14 get\_values()

```
template<typename ValueType = default_precision>
value_type* gko::matrix::Dense< ValueType >::get_values ( ) [inline], [noexcept]
```

Returns a pointer to the array of values of the matrix.

Returns

the pointer to the array of values

References gko::Array< ValueType >::get\_data().

Referenced by gko::matrix::Dense< ValueType >::create\_submatrix().

#### 26.27.2.15 scale()

Scales the matrix with a scalar (aka: BLAS scal).

#### **Parameters**

alpha

If alpha is 1x1 Dense matrix, the entire matrix is scaled by alpha. If it is a Dense row vector of values, then i-th column of the matrix is scaled with the i-th element of alpha (the number of columns of alpha has to match the number of columns of the matrix).

References gko::PolymorphicObject::get\_executor(), and gko::make\_temporary\_clone().

# 26.27.2.16 transpose()

```
template<typename ValueType = default_precision>
std::unique_ptr<LinOp> gko::matrix::Dense< ValueType >::transpose ( ) const [override],
[virtual]
```

Returns a LinOp representing the transpose of the Transposable object.

#### Returns

a pointer to the new transposed object

Implements gko::Transposable.

The documentation for this class was generated from the following files:

- ginkgo/core/matrix/coo.hpp (2f671dafa)
- ginkgo/core/matrix/dense.hpp (de9731922)

# 26.28 gko::dim< Dimensionality, DimensionType > Struct Template Reference

A type representing the dimensions of a multidimensional object.

```
#include <ginkgo/core/base/dim.hpp>
```

#### **Public Member Functions**

- constexpr dim (const dimension\_type &size=dimension\_type{})
  - Creates a dimension object with all dimensions set to the same value.
- template<typename... Rest> constexpr dim (const dimension type &first, const Rest &... rest)

Creates a dimension object with the specified dimensions.

- constexpr const dimension\_type & operator[] (const size\_type &dimension) const noexcept Returns the requested dimension.
- dimension type & operator[] (const size type &dimension) noexcept
- constexpr operator bool () const

Checks if all dimensions evaluate to true.

#### **Friends**

- constexpr friend bool operator== (const dim &x, const dim &y)
   Checks if two dim objects are equal.
- constexpr friend dim operator\* (const dim &x, const dim &y)
   Multiplies two dim objects.

## 26.28.1 Detailed Description

template < size\_type Dimensionality, typename DimensionType = size\_type > struct gko::dim < Dimensionality, DimensionType >

A type representing the dimensions of a multidimensional object.

#### **Template Parameters**

Dimensionality	number of dimensions of the object
DimensionType	datatype used to represent each dimension

#### 26.28.2 Constructor & Destructor Documentation

#### 26.28.2.1 dim() [1/2]

Creates a dimension object with all dimensions set to the same value.

## **Parameters**

```
size the size of each dimension
```

## 26.28.2.2 dim() [2/2]

Creates a dimension object with the specified dimensions.

If the number of dimensions given is less than the dimensionality of the object, the remaining dimensions are set to the same value as the last value given.

For example, in the context of matrices  $dim<2>\{2, 3\}$  creates the dimensions for a 2-by-3 matrix.

#### **Parameters**

first	first dimension
rest	other dimensions

## 26.28.3 Member Function Documentation

## 26.28.3.1 operator bool()

```
template<size_type Dimensionality, typename DimensionType = size_type>
constexpr gko::dim< Dimensionality, DimensionType >::operator bool () const [inline], [constexpr]
```

Checks if all dimensions evaluate to true.

For standard arithmetic types, this is equivalent to all dimensions being different than zero.

## Returns

true if and only if all dimensions evaluate to true

## 26.28.3.2 operator[]() [1/2]

Returns the requested dimension.

For example, if d is a dim<2> object representing matrix dimensions, d [0] returns the number of rows, and d [1] returns the number of columns.

#### **Parameters**

dimension	the requested dimension
-----------	-------------------------

## Returns

the dimension-th dimension

## 26.28.3.3 operator[]() [2/2]

## 26.28.4 Friends And Related Function Documentation

#### 26.28.4.1 operator\*

Multiplies two dim objects.

#### **Parameters**

X	first object
У	second object

## Returns

a dim object representing the size of the tensor product x \* y

## 26.28.4.2 operator==

Checks if two dim objects are equal.

## **Parameters**

Х	first object
У	second object

## Returns

true if and only if all dimensions of both objects are equal.

The documentation for this struct was generated from the following file:

• ginkgo/core/base/dim.hpp (f1a4eb68b)

## 26.29 gko::DimensionMismatch Class Reference

DimensionMismatch is thrown if an operation is being applied to LinOps of incompatible size.

```
#include <ginkgo/core/base/exception.hpp>
```

#### **Public Member Functions**

• DimensionMismatch (const std::string &file, int line, const std::string &func, const std::string &first\_name, size\_type first\_rows, size\_type first\_cols, const std::string &second\_name, size\_type second\_rows, size\_type second\_cols, const std::string &clarification)

Initializes a dimension mismatch error.

## 26.29.1 Detailed Description

DimensionMismatch is thrown if an operation is being applied to LinOps of incompatible size.

## 26.29.2 Constructor & Destructor Documentation

## 26.29.2.1 DimensionMismatch()

Initializes a dimension mismatch error.

## **Parameters**

file	The name of the offending source file
line	The source code line number where the error occurred
func	The function name where the error occurred
first_name	The name of the first operator
first_rows	The output dimension of the first operator
first_cols	The input dimension of the first operator
second_name	The name of the second operator
second_rows	The output dimension of the second operator
accord colo	The input dimension of the second energies

## 26.30 gko::matrix::Ell< ValueType, IndexType > Class Template Reference

ELL is a matrix format where stride with explicit zeros is used such that all rows have the same number of stored elements

#include <ginkgo/core/matrix/ell.hpp>

#### **Public Member Functions**

· void read (const mat data &data) override

Reads a matrix from a matrix\_data structure.

void write (mat\_data &data) const override

Writes a matrix to a matrix\_data structure.

value type \* get values () noexcept

Returns the values of the matrix.

const value\_type \* get\_const\_values () const noexcept

Returns the values of the matrix.

index\_type \* get\_col\_idxs () noexcept

Returns the column indexes of the matrix.

const index\_type \* get\_const\_col\_idxs () const noexcept

Returns the column indexes of the matrix.

• size\_type get\_num\_stored\_elements\_per\_row () const noexcept

Returns the number of stored elements per row.

• size type get stride () const noexcept

Returns the stride of the matrix.

size\_type get\_num\_stored\_elements () const noexcept

Returns the number of elements explicitly stored in the matrix.

value\_type & val\_at (size\_type row, size\_type idx) noexcept

Returns the idx-th non-zero element of the row-th row.

value\_type val\_at (size\_type row, size\_type idx) const noexcept

Returns the idx-th non-zero element of the row-th row.

index\_type & col\_at (size\_type row, size\_type idx) noexcept

Returns the idx-th column index of the row-th row.

index\_type col\_at (size\_type row, size\_type idx) const noexcept

Returns the idx-th column index of the row-th row.

## 26.30.1 Detailed Description

template<typename ValueType = default\_precision, typename IndexType = int32> class gko::matrix::EII< ValueType, IndexType >

ELL is a matrix format where stride with explicit zeros is used such that all rows have the same number of stored elements.

The number of elements stored in each row is the largest number of nonzero elements in any of the rows (obtainable through <a href="mailto:get\_num\_stored\_elements\_per\_row">get\_num\_stored\_elements\_per\_row</a>() method). This removes the need of a row pointer like in the CSR format, and allows for SIMD processing of the distinct rows. For efficient processing, the nonzero elements and the corresponding column indices are stored in column-major fashion. The columns are padded to the length by user-defined stride parameter whose default value is the number of rows of the matrix.

## **Template Parameters**

ValueType	precision of matrix elements
IndexType	precision of matrix indexes

## 26.30.2 Member Function Documentation

## 26.30.2.1 col\_at() [1/2]

Returns the idx-th column index of the row-th row.

#### **Parameters**

row	the row of the requested element
idx	the idx-th stored element of the row

## Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the OMP results in a runtime error)

```
209 {
210          return this->get_const_col_idxs()[this->linearize_index(row, idx)];
211    }
```

References gko::matrix::Ell< ValueType, IndexType >::get\_const\_col\_idxs().

## 26.30.2.2 col\_at() [2/2]

Returns the  ${\tt idx}\text{-th}$  column index of the  ${\tt row}\text{-th}$  row .

## **Parameters**

row	the row of the requested element
idx	the idx-th stored element of the row

Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the OMP results in a runtime error)

References gko::matrix::Ell< ValueType, IndexType >::get\_col\_idxs().

## 26.30.2.3 get\_col\_idxs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
index_type* gko::matrix::Ell< ValueType, IndexType >::get_col_idxs () [inline], [noexcept]
```

Returns the column indexes of the matrix.

#### Returns

the column indexes of the matrix.

References gko::Array< ValueType >::get\_data().

Referenced by gko::matrix::Ell< ValueType, IndexType >::col\_at().

### 26.30.2.4 get const col idxs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const index_type* gko::matrix::Ell< ValueType, IndexType >::get_const_col_idxs ( ) const [inline],
[noexcept]
```

Returns the column indexes of the matrix.

#### Returns

the column indexes of the matrix.

## Note

This is the constant version of the function, which can be significantly more memory efficient than the non-constant version, so always prefer this version.

References gko::Array< ValueType >::get\_const\_data().

Referenced by gko::matrix::Ell< ValueType, IndexType >::col\_at().

#### 26.30.2.5 get\_const\_values()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const value_type* gko::matrix::Ell< ValueType, IndexType >::get_const_values ( ) const [inline],
[noexcept]
```

Returns the values of the matrix.

#### Returns

the values of the matrix.

#### Note

This is the constant version of the function, which can be significantly more memory efficient than the non-constant version, so always prefer this version.

References gko::Array< ValueType >::get\_const\_data().

## 26.30.2.6 get\_num\_stored\_elements()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::Ell< ValueType, IndexType >::get_num_stored_elements ( ) const [inline],
[noexcept]
```

Returns the number of elements explicitly stored in the matrix.

## Returns

the number of elements explicitly stored in the matrix

References gko::Array< ValueType >::get\_num\_elems().

## 26.30.2.7 get\_num\_stored\_elements\_per\_row()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::Ell< ValueType, IndexType >::get_num_stored_elements_per_row ( ) const
[inline], [noexcept]
```

Returns the number of stored elements per row.

## Returns

the number of stored elements per row.

#### 26.30.2.8 get\_stride()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::Ell< ValueType, IndexType >::get_stride ( ) const [inline], [noexcept]
```

Returns the stride of the matrix.

#### **Returns**

the stride of the matrix.

#### 26.30.2.9 get values()

```
template<typename ValueType = default_precision, typename IndexType = int32>
value_type* gko::matrix::Ell< ValueType, IndexType >::get_values () [inline], [noexcept]
```

Returns the values of the matrix.

#### Returns

the values of the matrix.

References gko::Array< ValueType >::get\_data().

## 26.30.2.10 read()

Reads a matrix from a matrix data structure.

#### **Parameters**

```
data the matrix_data structure
```

Implements gko::ReadableFromMatrixData< ValueType, IndexType >.

### 26.30.2.11 val\_at() [1/2]

```
template<typename ValueType = default_precision, typename IndexType = int32>
value_type gko::matrix::Ell< ValueType, IndexType >::val_at (
```

```
size_type row,
size_type idx ) const [inline], [noexcept]
```

Returns the  ${\tt idx}\text{-th}$  non-zero element of the  ${\tt row}\text{-th}$  row .

#### **Parameters**

row	the row of the requested element
idx	the idx-th stored element of the row

#### Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the OMP results in a runtime error)

References gko::Array< ValueType >::get\_const\_data().

## 26.30.2.12 val\_at() [2/2]

Returns the idx-th non-zero element of the row-th row.

#### **Parameters**

row	the row of the requested element
idx	the idx-th stored element of the row

## Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the OMP results in a runtime error)

References gko::Array< ValueType >::get\_data().

## 26.30.2.13 write()

Writes a matrix to a matrix\_data structure.

## **Parameters**

data	the matrix_data structure
------	---------------------------

Implements gko::WritableToMatrixData< ValueType, IndexType >.

The documentation for this class was generated from the following files:

- ginkgo/core/matrix/csr.hpp (2f671dafa)
- ginkgo/core/matrix/ell.hpp (2f671dafa)

# 26.31 gko::enable\_parameters\_type< ConcreteParametersType, Factory > Struct Template Reference

The enable parameters type mixin is used to create a base implementation of the factory parameters structure.

```
#include <ginkgo/core/base/abstract_factory.hpp>
```

#### **Public Member Functions**

std::unique\_ptr< Factory > on (std::shared\_ptr< const Executor > exec) const
 Creates a new factory on the specified executor.

## 26.31.1 Detailed Description

```
template<typename ConcreteParametersType, typename Factory> struct gko::enable_parameters_type< ConcreteParametersType, Factory>
```

The enable\_parameters\_type mixin is used to create a base implementation of the factory parameters structure.

It provides only the on() method which can be used to instantiate the factory give the parameters stored in the structure.

## **Template Parameters**

ConcreteParametersType	the concrete parameters type which is being implemented [CRTP parameter]
Factory	the concrete factory for which these parameters are being used

#### 26.31.2 Member Function Documentation

#### 26.31.2.1 on()

Creates a new factory on the specified executor.

#### **Parameters**

exec the executor where the factory will be created

#### Returns

a new factory instance

The documentation for this struct was generated from the following file:

• ginkgo/core/base/abstract\_factory.hpp (97addc067)

# 26.32 gko::EnableAbstractPolymorphicObject< AbstactObject, PolymorphicBase > Class Template Reference

This mixin inherits from (a subclass of) PolymorphicObject and provides a base implementation of a new abstract object.

#include <ginkgo/core/base/polymorphic\_object.hpp>

## 26.32.1 Detailed Description

template<typename AbstactObject, typename PolymorphicBase = PolymorphicObject>
class gko::EnableAbstractPolymorphicObject< AbstactObject, PolymorphicBase >

This mixin inherits from (a subclass of) PolymorphicObject and provides a base implementation of a new abstract object.

It uses method hiding to update the parameter and return types from PolymorphicObject toAbstractObject` wherever it makes sense. As opposed to EnablePolymorphicObject, it does not implement PolymorphicObject's virtual methods.

## **Template Parameters**

AbstractObject	the abstract class which is being implemented [CRTP parameter]
PolymorphicBase	parent of AbstractObject in the polymorphic hierarchy, has to be a subclass of polymorphic
	object

#### See also

EnablePolymorphicObject for creating a concrete subclass of PolymorphicObject.

The documentation for this class was generated from the following file:

ginkgo/core/base/polymorphic\_object.hpp (8f70a7c81)

## 26.33 gko::EnableCreateMethod< ConcreteType > Class Template Reference

This mixin implements a static create() method on ConcreteType that dynamically allocates the memory, uses the passed-in arguments to construct the object, and returns an std::unique\_ptr to such an object.

#include <ginkgo/core/base/polymorphic\_object.hpp>

## 26.33.1 Detailed Description

template<typename ConcreteType> class gko::EnableCreateMethod< ConcreteType >

This mixin implements a static create() method on ConcreteType that dynamically allocates the memory, uses the passed-in arguments to construct the object, and returns an std::unique\_ptr to such an object.

**Template Parameters** 

ConcreteObject the concrete type for which create() is being implemented [CRTP parameter]

The documentation for this class was generated from the following file:

• ginkgo/core/base/polymorphic object.hpp (8f70a7c81)

# 26.34 gko::EnableDefaultFactory< ConcreteFactory, ProductType, ParametersType, PolymorphicBase > Class Template Reference

This mixin provides a default implementation of a concrete factory.

#include <ginkgo/core/base/abstract\_factory.hpp>

## **Public Member Functions**

• const parameters\_type & get\_parameters () const noexcept

Returns the parameters of the factory.

## **Static Public Member Functions**

• static parameters\_type create ()

Creates a new ParametersType object which can be used to instantiate a new ConcreteFactory.

## 26.34.1 Detailed Description

template < typename ConcreteFactory, typename ProductType, typename ParametersType, typename PolymorphicBase > class gko::EnableDefaultFactory < ConcreteFactory, ProductType, ParametersType, PolymorphicBase >

This mixin provides a default implementation of a concrete factory.

It implements all the methods of AbstractFactory and PolymorphicObject. Its implementation of the generate — \_impl() method delegates the creation of the product by calling the ProductType::ProductType(const ConcreteFactory \*, const components\_type &) constructor. The factory also supports parameters by using the ParametersType structure, which is defined by the user.

For a simple example, see IntFactory in core/test/base/abstract\_factory.cpp.

#### **Template Parameters**

the concrete factory which is being implemented [CRTP parameter]	
the concrete type of products which this factory produces, has to be a subclass of	
PolymorphicBase::abstract_product_type	
a type representing the parameters of the factory, has to inherit from the	
enable_parameters_type mixin	
parent of ConcreteFactory in the polymorphic hierarchy, has to be a subclass of AbstractFactory	

## 26.34.2 Member Function Documentation

## 26.34.2.1 create()

```
template<typename ConcreteFactory , typename ProductType , typename ParametersType , typename PolymorphicBase > static parameters_type gko::EnableDefaultFactory< ConcreteFactory, ProductType, Parameters← Type, PolymorphicBase >::create ( ) [inline], [static]
```

Creates a new ParametersType object which can be used to instantiate a new ConcreteFactory.

This method does not construct the factory directly, but returns a new parameters\_type object, which can be used to set the parameters of the factory. Once the parameters have been set, the parameters\_type::on() method can be used to obtain an instance of the factory with those parameters.

## Returns

a default parameters\_type object

#### 26.34.2.2 get parameters()

```
template<typename ConcreteFactory , typename ProductType , typename ParametersType , typename PolymorphicBase > const parameters_type& gko::EnableDefaultFactory< ConcreteFactory, ProductType, Parameters← Type, PolymorphicBase >::get_parameters ( ) const [inline], [noexcept]
```

Returns the parameters of the factory.

#### Returns

the parameters of the factory

The documentation for this class was generated from the following file:

ginkgo/core/base/abstract\_factory.hpp (97addc067)

# 26.35 gko::EnableLinOp< ConcreteLinOp, PolymorphicBase > Class Template Reference

The EnableLinOp mixin can be used to provide sensible default implementations of the majority of the LinOp and PolymorphicObject interface.

```
#include <ginkgo/core/base/lin_op.hpp>
```

## **Additional Inherited Members**

## 26.35.1 Detailed Description

```
template<typename ConcreteLinOp, typename PolymorphicBase = LinOp> class gko::EnableLinOp< ConcreteLinOp, PolymorphicBase >
```

The EnableLinOp mixin can be used to provide sensible default implementations of the majority of the LinOp and PolymorphicObject interface.

The goal of the mixin is to facilitate the development of new LinOp, by enabling the implementers to focus on the important parts of their operator, while the library takes care of generating the trivial utility functions. The mixin will provide default implementations for the entire PolymorphicObject interface, including a default implementation of copy\_from between objects of the new LinOp type. It will also hide the default LinOp::apply() methods with versions that preserve the static type of the object.

Implementers of new LinOps are required to specify only the following aspects:

- 1. Creation of the LinOp: This can be facilitated via either EnableCreateMethod mixin (used mostly for matrix formats), or GKO\_ENABLE\_LIN\_OP\_FACTORY macro (used for operators created from other operators, like preconditioners and solvers).
- 2. Application of the LinOp: Implementers have to override the two overloads of the LinOp::apply\_impl() virtual methods.

#### **Template Parameters**

ConcreteLinOp	the concrete LinOp which is being implemented [CRTP parameter]
PolymorphicBase	parent of ConcreteLinOp in the polymorphic hierarchy, has to be a subclass of LinOp

The documentation for this class was generated from the following file:

ginkgo/core/base/lin\_op.hpp (da7880906)

# 26.36 gko::log::EnableLogging < ConcreteLoggable, PolymorphicBase > Class Template Reference

EnableLogging is a mixin which should be inherited by any class which wants to enable logging.

#include <ginkgo/core/log/logger.hpp>

#### **Public Member Functions**

- void add\_logger (std::shared\_ptr< const Logger > logger) override
   Adds a new logger to the list of subscribed loggers.
- void remove\_logger (const Logger \*logger) override
   Removes a logger from the list of subscribed loggers.

## 26.36.1 Detailed Description

template<typename ConcreteLoggable, typename PolymorphicBase = Loggable> class gko::log::EnableLogging< ConcreteLoggable, PolymorphicBase>

EnableLogging is a mixin which should be inherited by any class which wants to enable logging.

All the received events are passed to the loggers this class contains.

## **Template Parameters**

ConcreteLoggable	the object being logged [CRTP parameter]	
PolymorphicBase	the polymorphic base of this class. By default it is Loggable. Change it if you want to use a new superclass of Loggable as polymorphic base of this class.	

## 26.36.2 Member Function Documentation

## 26.36.2.1 add\_logger()

Adds a new logger to the list of subscribed loggers.

#### **Parameters**

```
logger to add
```

## Implements gko::log::Loggable.

```
524 {
525 loggers_.push_back(logger);
526 }
```

## 26.36.2.2 remove\_logger()

Removes a logger from the list of subscribed loggers.

## Parameters

logger	the logger to remove

#### Note

The comparison is done using the logger's object unique identity. Thus, two loggers constructed in the same way are not considered equal.

Implements gko::log::Loggable.

The documentation for this class was generated from the following file:

• ginkgo/core/log/logger.hpp (0d7578c92)

# 26.37 gko::EnablePolymorphicAssignment< ConcreteType, ResultType > Class Template Reference

This mixin is used to enable a default PolymorphicObject::copy\_from() implementation for objects that have implemented conversions between them.

#include <ginkgo/core/base/polymorphic\_object.hpp>

#### **Public Member Functions**

- void convert\_to (result\_type \*result) const override
   Converts the implementer to an object of type result\_type.
- void move\_to (result\_type \*result) override

Converts the implementer to an object of type result\_type by moving data from this object.

## 26.37.1 Detailed Description

```
template<typename ConcreteType, typename ResultType = ConcreteType> class gko::EnablePolymorphicAssignment< ConcreteType, ResultType >
```

This mixin is used to enable a default PolymorphicObject::copy\_from() implementation for objects that have implemented conversions between them.

The requirement is that there is either a conversion constructor from ConcreteType in ResultType, or a conversion operator to ResultType in ConcreteType.

### **Template Parameters**

ConcreteType	the concrete type from which the copy_from is being enabled [CRTP parameter]
ResultType the type to which copy_from is being enabled	

## 26.37.2 Member Function Documentation

#### 26.37.2.1 convert\_to()

Converts the implementer to an object of type result\_type.

#### **Parameters**

```
result the object used to store the result of the conversion
```

Implements gko::ConvertibleTo < ResultType >.

## 26.37.2.2 move\_to()

Converts the implementer to an object of type result type by moving data from this object.

This method is used when the implementer is a temporary object, and move semantics can be used.

#### **Parameters**

result	the object used to emplace the result of the conversion
--------	---

Note

ConvertibleTo::move\_to can be implemented by simply calling ConvertibleTo::convert\_to. However, this operation can often be optimized by exploiting the fact that implementer's data can be moved to the result.

Implements gko::ConvertibleTo < ResultType >.

The documentation for this class was generated from the following file:

• ginkgo/core/base/polymorphic\_object.hpp (8f70a7c81)

# 26.38 gko::EnablePolymorphicObject< ConcreteObject, PolymorphicBase > Class Template Reference

This mixin inherits from (a subclass of) PolymorphicObject and provides a base implementation of a new concrete polymorphic object.

```
#include <ginkgo/core/base/polymorphic_object.hpp>
```

## 26.38.1 Detailed Description

```
template < typename ConcreteObject, typename PolymorphicBase = PolymorphicObject > class gko::EnablePolymorphicObject < ConcreteObject, PolymorphicBase >
```

This mixin inherits from (a subclass of) PolymorphicObject and provides a base implementation of a new concrete polymorphic object.

The mixin changes parameter and return types of appropriate public methods of PolymorphicObject in the same way EnableAbstractPolymorphicObject does. In addition, it also provides default implementations of PolymorphicObject's vritual methods by using the *executor default constructor* and the assignment operator of ConcreteObject. Consequently, the following is a minimal example of PolymorphicObject:

```
struct MyObject : EnablePolymorphicObject<MyObject> {
   MyObject(std::shared_ptr<const Executor> exec)
        : EnablePolymorphicObject<MyObject>(std::move(exec))
        {}
};
```

In a way, this mixin can be viewed as an extension of default constructor/destructor/assignment operators.

Note

This mixin does not enable copying the polymorphic object to the object of the same type (i.e. it does not implement the ConvertibleTo<ConcreteObject> interface). To enable a default implementation of this interface see the EnablePolymorphicAssignment mixin.

#### **Template Parameters**

ConcreteObject	the concrete type which is being implemented [CRTP parameter]
PolymorphicBase	parent of ConcreteObject in the polymorphic hierarchy, has to be a subclass of
	polymorphic object

The documentation for this class was generated from the following file:

• ginkgo/core/base/polymorphic object.hpp (8f70a7c81)

## 26.39 gko::Error Class Reference

The Error class is used to report exceptional behaviour in library functions.

```
#include <ginkgo/core/base/exception.hpp>
```

## **Public Member Functions**

- Error (const std::string &file, int line, const std::string &what)

  Initializes an error.
- virtual const char \* what () const noexcept override

Returns a human-readable string with a more detailed description of the error.

## 26.39.1 Detailed Description

The Error class is used to report exceptional behaviour in library functions.

Ginkgo uses C++ exception mechanism to this end, and the Error class represents a base class for all types of errors. The exact list of errors which could occur during the execution of a certain library routine is provided in the documentation of that routine, along with a short description of the situation when that error can occur. During runtime, these errors can be detected by using standard C++ try-catch blocks, and a human-readable error description can be obtained by calling the Error::what() method.

As an example, trying to compute a matrix-vector product with arguments of incompatible size will result in a DimensionMismatch error, which is demonstrated in the following program.

```
#include <ginkgo.h>
#include <iostream>
using namespace gko;
int main()
{
    auto omp = create<OmpExecutor>();
    auto A = randn_fill<matrix::Csr<float>(5, 5, 0f, 1f, omp);
    auto x = fill<matrix::Dense<float>(6, 1, 1f, omp);
    try {
        auto y = apply(A.get(), x.get());
    } catch(Error e) {
        // an error occured, write the message to screen and exit std::cout « e.what() « std::endl;
        return -1;
    }
    return 0;
```

#### 26.39.2 Constructor & Destructor Documentation

#### 26.39.2.1 Error()

Initializes an error.

#### **Parameters**

file	The name of the offending source file
line	The source code line number where the error occurred
what	The error message

The documentation for this class was generated from the following file:

• ginkgo/core/base/exception.hpp (6e8865457)

## 26.40 gko::Executor Class Reference

The first step in using the Ginkgo library consists of creating an executor.

```
#include <ginkgo/core/base/executor.hpp>
```

## **Public Member Functions**

- virtual void run (const Operation &op) const =0
  - Runs the specified Operation using this Executor.
- template < typename ClosureOmp , typename ClosureCuda > void run (const ClosureOmp & op\_omp, const ClosureCuda & op\_cuda) const

Runs one of the passed in functors, depending on the Executor type.

• template<typename T >

```
T * alloc (size_type num_elems) const
```

Allocates memory in this Executor.

Copies data from another Executor.

• void free (void \*ptr) const noexcept

Frees memory previously allocated with Executor::alloc().

• template<typename T >

 $void \ \, \textbf{copy\_from} \ \, (\textbf{const} \ \, \textbf{Executor} \ \, *\textbf{src\_exec}, \ \, \textbf{size\_type} \ \, \textbf{num\_elems}, \ \, \textbf{const} \ \, \textbf{T} \ \, *\textbf{src\_ptr}, \ \, \textbf{T} \ \, *\textbf{dest\_ptr}) \ \, \textbf{const} \ \, \textbf{const} \ \, \textbf{const} \ \, \textbf{T} \ \, *\textbf{dest\_ptr}) \ \, \textbf{const} \ \, \textbf{const} \ \, \textbf{T} \ \, *\textbf{dest\_ptr}) \ \, \textbf{const} \ \, \textbf{const} \ \, \textbf{T} \ \, *\textbf{dest\_ptr}) \ \, \textbf{const} \ \, \textbf{const} \ \, \textbf{T} \ \, *\textbf{dest\_ptr}) \ \, \textbf{const} \ \, \textbf{const} \ \, \textbf{T} \ \, *\textbf{dest\_ptr}) \ \, \textbf{const} \ \, \textbf{const} \ \, \textbf{T} \ \, *\textbf{dest\_ptr}) \ \, \textbf{const} \ \, \textbf{const} \ \, \textbf{T} \ \, *\textbf{dest\_ptr}) \ \, \textbf{const} \ \, \textbf{const} \ \, \textbf{T} \ \, *\textbf{dest\_ptr}) \ \, \textbf{const} \ \, \textbf{const} \ \, \textbf{T} \ \, *\textbf{dest\_ptr}) \ \, \textbf{const} \ \, \textbf{const} \ \, \textbf{T} \ \, *\textbf{dest\_ptr}) \ \, \textbf{const} \ \,$ 

virtual std::shared\_ptr< Executor > get\_master () noexcept=0

Returns the master OmpExecutor of this Executor.

virtual std::shared\_ptr< const Executor > get\_master () const noexcept=0

Returns the master OmpExecutor of this Executor.

virtual void synchronize () const =0

Synchronize the operations launched on the executor with its master.

## 26.40.1 Detailed Description

The first step in using the Ginkgo library consists of creating an executor.

Executors are used to specify the location for the data of linear algebra objects, and to determine where the operations will be executed. Ginkgo currently supports three different executor types:

- OmpExecutor specifies that the data should be stored and the associated operations executed on an Open
   — MP-supporting device (e.g. host CPU);
- CudaExecutor specifies that the data should be stored and the operations executed on the NVIDIA GPU accelerator;
- ReferenceExecutor executes a non-optimized reference implementation, which can be used to debug the library.

The following code snippet demonstrates the simplest possible use of the Ginkgo library:

```
auto omp = gko::create<gko::OmpExecutor>();
auto A = gko::read_from_mtx<gko::matrix::Csr<float»("A.mtx", omp);</pre>
```

First, we create a OMP executor, which will be used in the next line to specify where we want the data for the matrix A to be stored. The second line will read a matrix from the matrix market file 'A.mtx', and store the data on the CPU in CSR format (gko::matrix::Csr is a Ginkgo matrix class which stores its data in CSR format). At this point, matrix A is bound to the CPU, and any routines called on it will be performed on the CPU. This approach is usually desired in sparse linear algebra, as the cost of individual operations is several orders of magnitude lower than the cost of copying the matrix to the GPU.

If matrix A is going to be reused multiple times, it could be beneficial to copy it over to the accelerator, and perform the operations there, as demonstrated by the next code snippet:

```
auto cuda = gko::create<gko::CudaExecutor>(0, omp);
auto dA = gko::copy_to<gko::matrix::Csr<float»(A.get(), cuda);</pre>
```

The first line of the snippet creates a new CUDA executor. Since there may be multiple NVIDIA GPUs present on the system, the first parameter instructs the library to use the first device (i.e. the one with device ID zero, as in cudaSetDevice() routine from the CUDA runtime API). In addition, since GPUs are not stand-alone processors, it is required to pass a "master" OmpExecutor which will be used to schedule the requested CUDA kernels on the accelerator.

The second command creates a copy of the matrix A on the GPU. Notice the use of the get() method. As Ginkgo aims to provide automatic memory management of its objects, the result of calling gko::read\_from\_mtx() is a smart pointer (std::unique\_ptr) to the created object. On the other hand, as the library will not hold a reference to A once the copy is completed, the input parameter for gko::copy\_to() is a plain pointer. Thus, the get() method is used to convert from a std::unique\_ptr to a plain pointer, as expected by gko::copy\_to().

As a side note, the gko::copy\_to routine is far more powerful than just copying data between different devices. It can also be used to convert data between different formats. For example, if the above code used gko::matrix::Ell as the template parameter, dA would be stored on the GPU, in ELLPACK format.

Finally, if all the processing of the matrix is supposed to be done on the GPU, and a CPU copy of the matrix is not required, we could have read the matrix to the GPU directly:

```
auto omp = gko::create<gko::OmpExecutor>();
auto cuda = gko::create<gko::CudaExecutor>(0, omp);
auto dA = gko::read_from_mtx<gko::matrix::Csr<float>("A.mtx", cuda);
```

Notice that even though reading the matrix directly from a file to the accelerator is not supported, the library is designed to abstract away the intermediate step of reading the matrix to the CPU memory. This is a general design approach taken by the library: in case an operation is not supported by the device, the data will be copied to the CPU, the operation performed there, and finally the results copied back to the device. This approach makes using the library more concise, as explicit copies are not required by the user. Nevertheless, this feature should be taken into account when considering performance implications of using such operations.

## 26.40.2 Member Function Documentation

#### 26.40.2.1 alloc()

Allocates memory in this Executor.

## **Template Parameters**

```
T datatype to allocate
```

#### **Parameters**

num_elems	number of elements of type T to allocate
-----------	--

## **Exceptions**

```
AllocationError if the allocation failed
```

## Returns

pointer to allocated memory

## 26.40.2.2 copy\_from()

Copies data from another Executor.

## **Template Parameters**

```
T datatype to copy
```

## Parameters

src_exec	Executor from which the memory will be copied

#### **Parameters**

num_elems   number of elements of type T to copy	
src_ptr	pointer to a block of memory containing the data to be copied
dest_ptr	pointer to an allocated block of memory where the data will be copied to

## 26.40.2.3 free()

Frees memory previously allocated with Executor::alloc().

If ptr is a nullptr, the function has no effect.

#### **Parameters**

ptr pointer to the allocated memory block

## 26.40.2.4 get\_master() [1/2]

```
virtual std::shared_ptr<const Executor> gko::Executor::get_master ( ) const [pure virtual],
[noexcept]
```

Returns the master OmpExecutor of this Executor.

## Returns

the master OmpExecutor of this Executor.

Implemented in gko::CudaExecutor, and gko::OmpExecutor.

## 26.40.2.5 get\_master() [2/2]

```
virtual std::shared_ptr<Executor> gko::Executor::get_master ( ) [pure virtual], [noexcept]
```

Returns the master OmpExecutor of this Executor.

## Returns

the master OmpExecutor of this Executor.

Implemented in gko::CudaExecutor, and gko::OmpExecutor.

## 26.40.2.6 run() [1/2]

Runs one of the passed in functors, depending on the Executor type.

## **Template Parameters**

ClosureOmp	type of op_omp
ClosureCuda	type of op_cuda

#### **Parameters**

op_omp	functor to run in case of a OmpExecutor or ReferenceExecutor
op_cuda	functor to run in case of a CudaExecutor

References run().

## 26.40.2.7 run() [2/2]

Runs the specified Operation using this Executor.

## **Parameters**

```
op the operation to run
```

Implemented in gko::CudaExecutor, and gko::ReferenceExecutor.

Referenced by run().

The documentation for this class was generated from the following file:

• ginkgo/core/base/executor.hpp (8f70a7c81)

## 26.41 gko::log::executor\_data Struct Reference

Struct representing Executor related data.

#include <ginkgo/core/log/record.hpp>

## 26.41.1 Detailed Description

Struct representing Executor related data.

The documentation for this struct was generated from the following file:

• ginkgo/core/log/record.hpp (f0a50f96f)

## 26.42 gko::executor\_deleter< T > Class Template Reference

This is a deleter that uses an executor's free method to deallocate the data.

```
#include <ginkgo/core/base/executor.hpp>
```

## **Public Member Functions**

- executor\_deleter (std::shared\_ptr< const Executor > exec)
  - Creates a new deleter.
- void operator() (pointer ptr) const

Deletes the object.

## 26.42.1 Detailed Description

```
template<typename T> class gko::executor_deleter< T>
```

This is a deleter that uses an executor's free method to deallocate the data.

**Template Parameters** 

```
T the type of object being deleted
```

## 26.42.2 Constructor & Destructor Documentation

#### 26.42.2.1 executor\_deleter()

Creates a new deleter.

#### **Parameters**

exec the executor used to free the data

#### 26.42.3 Member Function Documentation

## 26.42.3.1 operator()()

Deletes the object.

#### **Parameters**

ptr pointer to the object being deleted

The documentation for this class was generated from the following file:

• ginkgo/core/base/executor.hpp (8f70a7c81)

## 26.43 gko::solver::Fcg< ValueType > Class Template Reference

FCG or the flexible conjugate gradient method is an iterative type Krylov subspace method which is suitable for symmetric positive definite methods.

```
#include <ginkgo/core/solver/fcg.hpp>
```

#### **Public Member Functions**

std::shared\_ptr< const LinOp > get\_system\_matrix () const
 Gets the system operator (matrix) of the linear system.

## 26.43.1 Detailed Description

```
template<typename ValueType = default_precision> class gko::solver::Fcg< ValueType >
```

FCG or the flexible conjugate gradient method is an iterative type Krylov subspace method which is suitable for symmetric positive definite methods.

Though this method performs very well for symmetric positive definite matrices, it is in general not suitable for general matrices.

In contrast to the standard CG based on the Polack-Ribiere formula, the flexible CG uses the Fletcher-Reeves formula for creating the orthonormal vectors spanning the Krylov subspace. This increases the computational cost of every Krylov solver iteration but allows for non-constant preconditioners.

The implementation in Ginkgo makes use of the merged kernel to make the best use of data locality. The inner operations in one iteration of FCG are merged into 2 separate steps.

#### **Template Parameters**

ValueType precis	ion of matrix elements
------------------	------------------------

#### 26.43.2 Member Function Documentation

## 26.43.2.1 get\_system\_matrix()

```
template<typename ValueType = default_precision>
std::shared_ptr<const LinOp> gko::solver::Fcg< ValueType >::get_system_matrix ( ) const [inline]
```

Gets the system operator (matrix) of the linear system.

#### Returns

the system operator (matrix)

The documentation for this class was generated from the following file:

• ginkgo/core/solver/fcg.hpp (4d55c5d34)

## 26.44 gko::solver::Gmres< ValueType > Class Template Reference

GMRES or the generalized minimal residual method is an iterative type Krylov subspace method which is suitable for nonsymmetric linear systems.

```
#include <ginkgo/core/solver/gmres.hpp>
```

### **Public Member Functions**

- std::shared\_ptr< const LinOp > get\_system\_matrix () const
- Gets the system operator (matrix) of the linear system.

• size\_type get\_krylov\_dim () const

Returns the krylov dimension.

## 26.44.1 Detailed Description

```
template<typename ValueType = default_precision> class gko::solver::Gmres< ValueType >
```

GMRES or the generalized minimal residual method is an iterative type Krylov subspace method which is suitable for nonsymmetric linear systems.

The implementation in Ginkgo makes use of the merged kernel to make the best use of data locality. The inner operations in one iteration of GMRES are merged into 2 separate steps.

#### **Template Parameters**

ValueType	precision of matrix elements
-----------	------------------------------

#### 26.44.2 Member Function Documentation

## 26.44.2.1 get\_krylov\_dim()

```
template<typename ValueType = default_precision>
size_type gko::solver::Gmres< ValueType >::get_krylov_dim ( ) const [inline]
```

Returns the krylov dimension.

#### Returns

the krylov dimension

```
94 { return krylov_dim_; }
```

## 26.44.2.2 get\_system\_matrix()

```
template<typename ValueType = default_precision>
std::shared_ptr<const LinOp> gko::solver::Gmres< ValueType >::get_system_matrix ( ) const
[inline]
```

Gets the system operator (matrix) of the linear system.

## Returns

the system operator (matrix)

The documentation for this class was generated from the following file:

• ginkgo/core/solver/gmres.hpp (4d55c5d34)

## 26.45 gko::matrix::Hybrid< ValueType, IndexType > Class Template Reference

HYBRID is a matrix format which splits the matrix into ELLPACK and COO format.

#include <ginkgo/core/matrix/hybrid.hpp>

#### Classes

· class automatic

automatic is a stratgy\_type which decides the number of stored elements per row of the ell part automatically.

· class column limit

column\_limit is a strategy\_type which decides the number of stored elements per row of the ell part by specifying the number of columns.

· class imbalance bounded limit

imbalance bounded limit is a stratgy type which decides the number of stored elements per row of the ell part.

· class imbalance limit

imbalance\_limit is a strategy\_type which decides the number of stored elements per row of the ell part according to the percent.

class minimal\_storage\_limit

minimal\_storage\_limit is a stratgy\_type which decides the number of stored elements per row of the ell part.

· class strategy type

strategy\_type is to decide how to set the hybrid config.

#### **Public Member Functions**

void read (const mat\_data &data) override

Reads a matrix from a matrix\_data structure.

void write (mat\_data &data) const override

Writes a matrix to a matrix\_data structure.

value\_type \* get\_ell\_values () noexcept

Returns the values of the ell part.

const value\_type \* get\_const\_ell\_values () const noexcept

Returns the values of the ell part.

index\_type \* get\_ell\_col\_idxs () noexcept

Returns the column indexes of the ell part.

• const index type \* get const ell col idxs () const noexcept

Returns the column indexes of the ell part.

• size\_type get\_ell\_num\_stored\_elements\_per\_row () const noexcept

Returns the number of stored elements per row of ell part.

• size\_type get\_ell\_stride () const noexcept

Returns the stride of the ell part.

• size\_type get\_ell\_num\_stored\_elements () const noexcept

Returns the number of elements explicitly stored in the ell part.

value\_type & ell\_val\_at (size\_type row, size\_type idx) noexcept

Returns the idx-th non-zero element of the row-th row in the ell part.

value\_type ell\_val\_at (size\_type row, size\_type idx) const noexcept
 Returns the idx-th non-zero element of the row-th row in the ell part.

• index\_type & ell\_col\_at (size\_type row, size\_type idx) noexcept

Returns the idx-th column index of the row-th row in the ell part.

index\_type ell\_col\_at (size\_type row, size\_type idx) const noexcept

Returns the idx-th column index of the row-th row in the ell part.

const ell\_type \* get\_ell () const noexcept

Returns the matrix of the ell part.

value\_type \* get\_coo\_values () noexcept

Returns the values of the coo part.

• const value type \* get const coo values () const noexcept

Returns the values of the coo part.

index\_type \* get\_coo\_col\_idxs () noexcept

Returns the column indexes of the coo part.

const index\_type \* get\_const\_coo\_col\_idxs () const noexcept

Returns the column indexes of the coo part.

index\_type \* get\_coo\_row\_idxs () noexcept

Returns the row indexes of the coo part.

const index\_type \* get\_const\_coo\_row\_idxs () const noexcept

Returns the row indexes of the coo part.

size\_type get\_coo\_num\_stored\_elements () const noexcept

Returns the number of elements explicitly stored in the coo part.

const coo\_type \* get\_coo () const noexcept

Returns the matrix of the coo part.

size\_type get\_num\_stored\_elements () const noexcept

Returns the number of elements explicitly stored in the matrix.

- std::shared\_ptr< strategy\_type > get\_strategy () const noexcept
   Returns the strategy.
- Hybrid & operator= (const Hybrid &other)

Copies data from another Hybrid.

## 26.45.1 Detailed Description

template<typename ValueType = default\_precision, typename IndexType = int32> class gko::matrix::Hybrid< ValueType, IndexType >

HYBRID is a matrix format which splits the matrix into ELLPACK and COO format.

Achieve the excellent performance with a proper partition of ELLPACK and COO.

## **Template Parameters**

ValueType	precision of matrix elements
IndexType	precision of matrix indexes

#### 26.45.2 Member Function Documentation

## 26.45.2.1 ell col at() [1/2]

Returns the idx-th column index of the row-th row in the ell part.

#### **Parameters**

row	the row of the requested element
idx	the idx-th stored element of the row

#### Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the OMP results in a runtime error)

## 26.45.2.2 ell\_col\_at() [2/2]

Returns the idx-th column index of the row-th row in the ell part.

#### **Parameters**

row	the row of the requested element
idx	the idx-th stored element of the row

#### Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the OMP results in a runtime error)

#### 26.45.2.3 ell\_val\_at() [1/2]

Returns the idx-th non-zero element of the row-th row in the ell part.

#### **Parameters**

row	the row of the requested element
idx	the idx-th stored element of the row

#### Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the OMP results in a runtime error)

## 26.45.2.4 ell\_val\_at() [2/2]

Returns the idx-th non-zero element of the row-th row in the ell part.

#### **Parameters**

row	the row of the requested element
idx	the idx-th stored element of the row

#### Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the OMP results in a runtime error)

## 26.45.2.5 get\_const\_coo\_col\_idxs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const index_type* gko::matrix::Hybrid< ValueType, IndexType >::get_const_coo_col_idxs ( )
const [inline], [noexcept]
```

Returns the column indexes of the coo part.

## Returns

the column indexes of the coo part.

## Note

This is the constant version of the function, which can be significantly more memory efficient than the non-constant version, so always prefer this version.

## 26.45.2.6 get\_const\_coo\_row\_idxs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const index_type* gko::matrix::Hybrid< ValueType, IndexType >::get_const_coo_row_idxs ( )
const [inline], [noexcept]
```

Returns the row indexes of the coo part.

#### Returns

the row indexes of the coo part.

#### Note

This is the constant version of the function, which can be significantly more memory efficient than the non-constant version, so always prefer this version.

## 26.45.2.7 get\_const\_coo\_values()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const value_type* gko::matrix::Hybrid< ValueType, IndexType >::get_const_coo_values ( ) const
[inline], [noexcept]
```

Returns the values of the coo part.

## Returns

the values of the coo part.

#### Note

This is the constant version of the function, which can be significantly more memory efficient than the non-constant version, so always prefer this version.

## 26.45.2.8 get\_const\_ell\_col\_idxs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const index_type* gko::matrix::Hybrid< ValueType, IndexType >::get_const_ell_col_idxs ( )
const [inline], [noexcept]
```

Returns the column indexes of the ell part.

#### Returns

the column indexes of the ell part

## Note

This is the constant version of the function, which can be significantly more memory efficient than the non-constant version, so always prefer this version.

## 26.45.2.9 get\_const\_ell\_values()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const value_type* gko::matrix::Hybrid< ValueType, IndexType >::get_const_ell_values ( ) const
[inline], [noexcept]
```

Returns the values of the ell part.

#### Returns

the values of the ell part

#### Note

This is the constant version of the function, which can be significantly more memory efficient than the non-constant version, so always prefer this version.

## 26.45.2.10 get\_coo()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const coo_type* gko::matrix::Hybrid< ValueType, IndexType >::get_coo ( ) const [inline],
[noexcept]
```

Returns the matrix of the coo part.

## Returns

the matrix of the coo part

## 26.45.2.11 get\_coo\_col\_idxs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
index_type* gko::matrix::Hybrid< ValueType, IndexType >::get_coo_col_idxs ( ) [inline], [noexcept]
```

Returns the column indexes of the coo part.

#### Returns

the column indexes of the coo part.

## 26.45.2.12 get\_coo\_num\_stored\_elements()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::Hybrid< ValueType, IndexType >::get_coo_num_stored_elements ( ) const
[inline], [noexcept]
```

Returns the number of elements explicitly stored in the coo part.

## Returns

the number of elements explicitly stored in the coo part

## 26.45.2.13 get\_coo\_row\_idxs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
index_type* gko::matrix::Hybrid< ValueType, IndexType >::get_coo_row_idxs ( ) [inline], [noexcept]
```

Returns the row indexes of the coo part.

## Returns

the row indexes of the coo part.

## 26.45.2.14 get\_coo\_values()

```
template<typename ValueType = default_precision, typename IndexType = int32>
value_type* gko::matrix::Hybrid< ValueType, IndexType >::get_coo_values () [inline], [noexcept]
```

Returns the values of the coo part.

## Returns

the values of the coo part.

## 26.45.2.15 get\_ell()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const ell_type* gko::matrix::Hybrid< ValueType, IndexType >::get_ell ( ) const [inline],
[noexcept]
```

Returns the matrix of the ell part.

## Returns

the matrix of the ell part

## 26.45.2.16 get\_ell\_col\_idxs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
index_type* gko::matrix::Hybrid< ValueType, IndexType >::get_ell_col_idxs ( ) [inline], [noexcept]
```

Returns the column indexes of the ell part.

#### Returns

the column indexes of the ell part

#### 26.45.2.17 get ell num stored elements()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::Hybrid< ValueType, IndexType >::get_ell_num_stored_elements ( ) const
[inline], [noexcept]
```

Returns the number of elements explicitly stored in the ell part.

#### Returns

the number of elements explicitly stored in the ell part

## 26.45.2.18 get\_ell\_num\_stored\_elements\_per\_row()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::Hybrid< ValueType, IndexType >::get_ell_num_stored_elements_per_row ( )
const [inline], [noexcept]
```

Returns the number of stored elements per row of ell part.

## Returns

the number of stored elements per row of ell part

## 26.45.2.19 get\_ell\_stride()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::Hybrid< ValueType, IndexType >::get_ell_stride ( ) const [inline],
[noexcept]
```

Returns the stride of the ell part.

### Returns

the stride of the ell part

## 26.45.2.20 get\_ell\_values()

```
template<typename ValueType = default_precision, typename IndexType = int32>
value_type* gko::matrix::Hybrid< ValueType, IndexType >::get_ell_values () [inline], [noexcept]
```

Returns the values of the ell part.

#### Returns

the values of the ell part

## 26.45.2.21 get\_num\_stored\_elements()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::Hybrid< ValueType, IndexType >::get_num_stored_elements ( ) const
[inline], [noexcept]
```

Returns the number of elements explicitly stored in the matrix.

## Returns

the number of elements explicitly stored in the matrix

## 26.45.2.22 get\_strategy()

```
template<typename ValueType = default_precision, typename IndexType = int32>
std::shared_ptr<strategy_type> gko::matrix::Hybrid< ValueType, IndexType >::get_strategy ( )
const [inline], [noexcept]
```

Returns the strategy.

#### Returns

the strategy

## 26.45.2.23 operator=()

Copies data from another Hybrid.

#### **Parameters**

other the Hybrid to copy from

#### Returns

this

## 26.45.2.24 read()

Reads a matrix from a matrix\_data structure.

#### **Parameters**

data the matrix\_data structure

Implements gko::ReadableFromMatrixData< ValueType, IndexType >.

## 26.45.2.25 write()

Writes a matrix to a matrix data structure.

#### **Parameters**

```
data the matrix_data structure
```

Implements gko::WritableToMatrixData< ValueType, IndexType >.

The documentation for this class was generated from the following files:

- ginkgo/core/matrix/csr.hpp (2f671dafa)
- ginkgo/core/matrix/hybrid.hpp (4b82e692f)

# 26.46 gko::matrix::ldentity < ValueType > Class Template Reference

This class is a utility which efficiently implements the identity matrix (a linear operator which maps each vector to itself).

#include <ginkgo/core/matrix/identity.hpp>

#### **Additional Inherited Members**

## 26.46.1 Detailed Description

```
template<typename ValueType = default_precision> class gko::matrix::ldentity< ValueType >
```

This class is a utility which efficiently implements the identity matrix (a linear operator which maps each vector to itself).

Thus, objects of the Identity class always represent a square matrix, and don't require any storage for their values. The apply method is implemented as a simple copy (or a linear combination).

#### Note

This class is useful when composing it with other operators. For example, it can be used instead of a preconditioner in Krylov solvers, if one wants to run a "plain" solver, without using a preconditioner.

#### **Template Parameters**

ValueType	precision of matrix elements	
-----------	------------------------------	--

The documentation for this class was generated from the following file:

ginkgo/core/matrix/identity.hpp (8045ac753)

# 26.47 gko::matrix::ldentityFactory< ValueType > Class Template Reference

This factory is a utility which can be used to generate Identity operators.

```
#include <ginkgo/core/matrix/identity.hpp>
```

## **Static Public Member Functions**

static std::unique\_ptr< IdentityFactory > create (std::shared\_ptr< const Executor > exec)
 Creates a new Identity factory.

## **Additional Inherited Members**

## 26.47.1 Detailed Description

```
template<typename ValueType = default_precision> class gko::matrix::ldentityFactory< ValueType >
```

This factory is a utility which can be used to generate Identity operators.

The factory will generate the Identity matrix with the same dimension as the passed in operator. It will throw an exception if the operator is not square.

## **Template Parameters**

ValueType | precision of matrix elements

## 26.47.2 Member Function Documentation

#### 26.47.2.1 create()

Creates a new Identity factory.

## **Parameters**

exec the executor where the Identity operator will be stored

#### Returns

a unique pointer to the newly created factory

The documentation for this class was generated from the following file:

• ginkgo/core/matrix/identity.hpp (8045ac753)

# 26.48 gko::preconditioner::llu< LSolverType, USolverType, ReverseApply, IndexTypeParllu > Class Template Reference

The Incomplete LU (ILU) preconditioner solves the equation LUx = b for a given lower triangular matrix L, an upper triangular matrix U and the right hand side b (can contain multiple right hand sides).

```
#include <ginkgo/core/preconditioner/ilu.hpp>
```

## **Public Member Functions**

- std::shared\_ptr< const l\_solver\_type > get\_l\_solver () const Returns the solver which is used for the provided L matrix.
- std::shared\_ptr< const u\_solver\_type > get\_u\_solver () const

Returns the solver which is used for the provided U matrix.

## 26.48.1 Detailed Description

 $template < typename\ LSolverType = solver:: LowerTrs <>,\ typename\ USolverType = solver:: UpperTrs <>,\ bool\ ReverseApply = false,\ typename\ IndexTypeParlIu = int32>$ 

class gko::preconditioner::llu< LSolverType, USolverType, ReverseApply, IndexTypeParllu >

The Incomplete LU (ILU) preconditioner solves the equation LUx = b for a given lower triangular matrix L, an upper triangular matrix U and the right hand side b (can contain multiple right hand sides).

It allows to set both the solver for L and the solver for U independently, while providing the defaults solver::LowerTrs and solver::UpperTrs, which are direct triangular solvers. For these solvers, a factory can be provided (with with  $\_l\_solver\_factory$ ) to have more control over their behavior. In particular, it is possible to use an iterative method for solving the triangular systems. The default parameters for an iterative triangluar solver are:

- reduction factor = 1e-4
- max iteration = <number of="" rows="" of="" the="" matrix="" given="" to="" the="" solver>=""> Solvers without such criteria can also be used, in which case none are set.

An object of this class can be created with a matrix or a gko::Composition containing two matrices. If created with a matrix, it is factorized before creating the solver. If a gko::Composition (containing two matrices) is used, the first operand will be taken as the L matrix, the second will be considered the U matrix. Parllu can be directly used, since it orders the factors in the correct way.

#### Note

When providing a gko::Composition, the first matrix must be the lower matrix (L), and the second matrix must be the upper matrix (U). If they are swapped, solving might crash or return the wrong result.

Do not use symmetric solvers (like CG) for L or U solvers since both matrices (L and U) are, by design, not symmetric.

This class is not thread safe (even a const object is not) because it uses an internal cache to accelerate multiple (sequential) applies. Using it in parallel can lead to segmentation faults, wrong results and other unwanted behavior.

## **Template Parameters**

LSolverType	type of the solver used for the L matrix. Defaults to solver::LowerTrs
USolverType	type of the solver used for the U matrix Defaults to solver::UpperTrs
ReverseApply	default behavior (ReverseApply = false) is first to solve with L (Ly = b) and then with U (Ux = y). When set to true, it will solve first with U, and then with L.
IndexTypeParllu	Type of the indices when Parllu is used to generate both L and U factors. Irrelevant otherwise.

## 26.48.2 Member Function Documentation

## 26.48.2.1 get\_l\_solver()

```
template<typename LSolverType = solver::LowerTrs<>, typename USolverType = solver::Upper←
Trs<>, bool ReverseApply = false, typename IndexTypeParIlu = int32>
std::shared_ptr<const l_solver_type> gko::preconditioner::Ilu< LSolverType, USolverType,
ReverseApply, IndexTypeParIlu >::get_l_solver () const [inline]
```

Returns the solver which is used for the provided L matrix.

#### Returns

the solver which is used for the provided L matrix

## 26.48.2.2 get\_u\_solver()

```
template<typename LSolverType = solver::LowerTrs<>, typename USolverType = solver::Upper←
Trs<>, bool ReverseApply = false, typename IndexTypeParIlu = int32>
std::shared_ptr<const u_solver_type> gko::preconditioner::Ilu< LSolverType, USolverType,
ReverseApply, IndexTypeParIlu >::get_u_solver () const [inline]
```

Returns the solver which is used for the provided U matrix.

#### Returns

the solver which is used for the provided U matrix

The documentation for this class was generated from the following file:

• ginkgo/core/preconditioner/ilu.hpp (638db8ca9)

# 26.49 gko::matrix::Hybrid< ValueType, IndexType >::imbalance\_bounded\_limit Class Reference

imbalance bounded limit is a stratgy type which decides the number of stored elements per row of the ell part.

```
#include <ginkgo/core/matrix/hybrid.hpp>
```

## **Public Member Functions**

   Creates a imbalance\_bounded\_limit strategy.
- size\_type compute\_ell\_num\_stored\_elements\_per\_row (Array< size\_type > \*row\_nnz) const override

  Computes the number of stored elements per row of the ell part.

## 26.49.1 Detailed Description

template < typename ValueType = default\_precision, typename IndexType = int32 > class gko::matrix::Hybrid < ValueType, IndexType >::imbalance\_bounded\_limit

imbalance\_bounded\_limit is a stratgy\_type which decides the number of stored elements per row of the ell part.

It uses the imbalance limit and adds the upper bound of the number of ell's cols by the number of rows.

## 26.49.2 Member Function Documentation

#### 26.49.2.1 compute\_ell\_num\_stored\_elements\_per\_row()

Computes the number of stored elements per row of the ell part.

#### **Parameters**

row nnz	the number of nonzeros of each row

## Returns

the number of stored elements per row of the ell part

Implements gko::matrix::Hybrid< ValueType, IndexType >::strategy type.

References gko::matrix::Hybrid< ValueType, IndexType >::imbalance\_limit::compute\_ell\_num\_stored\_elements ← \_\_per\_row(), and gko::Array< ValueType >::get\_num\_elems().

Referenced by gko::matrix::Hybrid < ValueType, IndexType >::automatic::compute\_ell\_num\_stored\_elements\_ $\leftarrow$  per\_row().

The documentation for this class was generated from the following file:

• ginkgo/core/matrix/hybrid.hpp (4b82e692f)

# 26.50 gko::matrix::Hybrid< ValueType, IndexType >::imbalance\_limit Class Reference

imbalance\_limit is a strategy\_type which decides the number of stored elements per row of the ell part according to the percent.

#include <ginkgo/core/matrix/hybrid.hpp>

#### **Public Member Functions**

- imbalance\_limit (float percent=0.8)
  - Creates a imbalance\_limit strategy.
- size\_type compute\_ell\_num\_stored\_elements\_per\_row (Array< size\_type > \*row\_nnz) const override

  Computes the number of stored elements per row of the ell part.

## 26.50.1 Detailed Description

```
template<typename ValueType = default_precision, typename IndexType = int32> class gko::matrix::Hybrid< ValueType, IndexType >::imbalance_limit
```

imbalance\_limit is a strategy\_type which decides the number of stored elements per row of the ell part according to the percent.

It sorts the number of nonzeros of each row and takes the value at the position floor (percent \* num\_row) as the number of stored elements per row of the ell part. Thus, at least percent rows of all are in the ell part.

## 26.50.2 Constructor & Destructor Documentation

## 26.50.2.1 imbalance\_limit()

Creates a imbalance\_limit strategy.

#### **Parameters**

percent the row\_nnz[floor(num\_rows\*percent)] is the number of stored elements per row of the ell part

## 26.50.3 Member Function Documentation

## 26.50.3.1 compute\_ell\_num\_stored\_elements\_per\_row()

Computes the number of stored elements per row of the ell part.

#### **Parameters**

row_nnz	the number of nonzeros of each row	
---------	------------------------------------	--

## Returns

the number of stored elements per row of the ell part

Implements gko::matrix::Hybrid< ValueType, IndexType >::strategy\_type.

References gko::Array < ValueType >::get\_data(), and gko::Array < ValueType >::get\_num\_elems().

Referenced by gko::matrix::Hybrid< ValueType, IndexType >::imbalance\_bounded\_limit::compute\_ell\_num\_ $\hookleftarrow$  stored\_elements\_per\_row(), and gko::matrix::Hybrid< ValueType, IndexType >::minimal\_storage\_limit::compute  $\hookleftarrow$  \_ell\_num\_stored\_elements\_per\_row().

## 26.51 gko::solver::lr < ValueType > Class Template Reference

Iterative refinement (IR) is an iterative method that uses another coarse method to approximate the error of the current solution via the current residual.

#include <ginkgo/core/solver/ir.hpp>

## **Public Member Functions**

• std::shared\_ptr< const LinOp > get\_system\_matrix () const

Returns the system operator (matrix) of the linear system.

• std::shared\_ptr< const LinOp > get\_solver () const

Returns the solver operator used as the inner solver.

void set solver (std::shared ptr< const LinOp > new solver)

Sets the solver operator used as the inner solver.

## 26.51.1 Detailed Description

```
\label{template} $$ \ensuremath{\sf template}$$ < \ensuremath{\sf type}$ = \ensuremath{\sf default\_precision}$> $$ \ensuremath{\sf class}$ \ensuremath{\sf gko}$::solver::Ir< \ensuremath{\sf ValueType}$>
```

Iterative refinement (IR) is an iterative method that uses another coarse method to approximate the error of the current solution via the current residual.

For any approximation of the solution solution to the system Ax = b, the residual is defined as: residual = b - A solution. The error in solution, e = x - solution (with x being the exact solution) can be obtained as the solution to the residual equation Ae = residual, since Ae = Ax - A solution = b - A solution = residual. Then, the real solution is computed as x = solution + e. Instead of accurately solving the residual equation Ae = residual, the solution of the system e can be approximated to obtain the approximation error using a coarse method solver, which is used to update solution, and the entire process is repeated with the updated solution. This yields the iterative refinement method:

```
solution = initial_guess
while not converged:
    residual = b - A solution
    error = solver(A, residual)
    solution = solution + error
```

Assuming that solver has accuracy c, i.e., | e - error | <= c | e |, iterative refinement will converge with a convergence rate of c. Indeed, from e - error = x - solution - error = x - solution\* (where solution\* denotes the value stored in solution after the update) and <math>e = inv(A) residual = inv(A)b - inv(A) A solution = x - solution it follows that | x - solution\* | <= c | x - solution |.

Unless otherwise specified via the solver factory parameter, this implementation uses the identity operator (i.e. the solver that approximates the solution of a system Ax = b by setting x := b) as the default inner solver. Such a setting results in a relaxation method known as the Richardson iteration with parameter 1, which is guaranteed to converge for matrices whose spectrum is strictly contained within the unit disc around 1 (i.e., all its eigenvalues lambda have to satisfy the equation |a| = 1.

## **Template Parameters**

```
ValueType precision of matrix elements
```

## 26.51.2 Member Function Documentation

## 26.51.2.1 get\_solver()

```
template<typename ValueType = default_precision>
std::shared_ptr<const LinOp> gko::solver::Ir< ValueType >::get_solver ( ) const [inline]
```

Returns the solver operator used as the inner solver.

#### Returns

the solver operator used as the inner solver

```
117 { return solver_; }
```

## 26.51.2.2 get\_system\_matrix()

```
template<typename ValueType = default_precision>
std::shared_ptr<const LinOp> gko::solver::Ir< ValueType >::get_system_matrix ( ) const [inline]
```

Returns the system operator (matrix) of the linear system.

Returns

the system operator (matrix)

## 26.51.2.3 set solver()

Sets the solver operator used as the inner solver.

**Parameters** 

new\_solver the new inner solver

The documentation for this class was generated from the following file:

• ginkgo/core/solver/ir.hpp (ff3f14fec)

# 26.52 gko::stop::Iteration Class Reference

The Iteration class is a stopping criterion which stops the iteration process after a preset number of iterations.

```
#include <ginkgo/core/stop/iteration.hpp>
```

## 26.52.1 Detailed Description

The Iteration class is a stopping criterion which stops the iteration process after a preset number of iterations.

Note

to use this stopping criterion, it is required to update the iteration count for the ::check() method.

The documentation for this class was generated from the following file:

const remove\_complex< value\_type > \* get\_conditioning () const noexcept

Returns an array of 1-norm condition numbers of the blocks.

• size\_type get\_num\_stored\_elements () const noexcept

Returns the number of elements explicitly stored in the matrix.

void convert\_to (matrix::Dense< value\_type > \*result) const override

Converts the implementer to an object of type result\_type.

void move\_to (matrix::Dense< value\_type > \*result) override

Converts the implementer to an object of type result\_type by moving data from this object.

void write (mat\_data &data) const override

Writes a matrix to a matrix\_data structure.

## 26.54.1 Detailed Description

template<typename ValueType = default\_precision, typename IndexType = int32> class gko::preconditioner::Jacobi< ValueType, IndexType >

A block-Jacobi preconditioner is a block-diagonal linear operator, obtained by inverting the diagonal blocks of the source operator.

The Jacobi class implements the inversion of the diagonal blocks using Gauss-Jordan elimination with column pivoting, and stores the inverse explicitly in a customized format.

If the diagonal blocks of the matrix are not explicitly set by the user, the implementation will try to automatically detect the blocks by first finding the natural blocks of the matrix, and then applying the supervariable agglomeration procedure on them. However, if problem-specific knowledge regarding the block diagonal structure is available, it is usually beneficial to explicitly pass the starting rows of the diagonal blocks, as the block detection is merely a heuristic and cannot perfectly detect the diagonal block structure. The current implementation supports blocks of up to 32 rows / columns.

The implementation also includes an improved, adaptive version of the block-Jacobi preconditioner, which can store some of the blocks in lower precision and thus improve the performance of preconditioner application by reducing the amount of memory transfers. This variant can be enabled by setting the Jacobi::Factory's storage optimization parameter. Refer to the documentation of the parameter for more details.

#### **Template Parameters**

ValueType	precision of matrix elements
IndexType	integral type used to store pointers to the start of each block

#### Note

The current implementation supports blocks of up to 32 rows / columns.

When using the adaptive variant, there may be a trade-off in terms of slightly longer preconditioner generation due to extra work required to detect the optimal precision of the blocks.

## 26.54.2 Member Function Documentation

## 26.54.2.1 convert\_to()

Converts the implementer to an object of type result type.

#### **Parameters**

result	the object used to store the result of the conversion
--------	---

Implements gko::ConvertibleTo< matrix::Dense< ValueType >>.

#### 26.54.2.2 get blocks()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const value_type* gko::preconditioner::Jacobi< ValueType, IndexType >::get_blocks ( ) const
[inline], [noexcept]
```

Returns the pointer to the memory used for storing the block data.

Element (i, j) of block b is stored in position (get\_block\_pointers() [b] + i) \* stride + j of the array.

#### Returns

the pointer to the memory used for storing the block data

References gko::Array< ValueType >::get\_const\_data().

## 26.54.2.3 get\_conditioning()

```
template<typename ValueType = default_precision, typename IndexType = int32> const remove_complex<value_type>* gko::preconditioner::Jacobi< ValueType, IndexType >::get_← conditioning ( ) const [inline], [noexcept]
```

Returns an array of 1-norm condition numbers of the blocks.

#### Returns

an array of 1-norm condition numbers of the blocks

## Note

This value is valid only if adaptive precision variant is used, and implementations of the standard non-adaptive variant are allowed to omit the calculation of condition numbers.

References gko::Array< ValueType >::get\_const\_data().

## 26.54.2.4 get\_num\_blocks()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::preconditioner::Jacobi < ValueType, IndexType >::get_num_blocks ( ) const [inline],
[noexcept]
```

Returns the number of blocks of the operator.

## Returns

the number of blocks of the operator

## 26.54.2.5 get\_num\_stored\_elements()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::preconditioner::Jacobi< ValueType, IndexType >::get_num_stored_elements ( )
const [inline], [noexcept]
```

Returns the number of elements explicitly stored in the matrix.

#### Returns

the number of elements explicitly stored in the matrix

References gko::Array < ValueType >::get\_num\_elems().

## 26.54.2.6 get\_storage\_scheme()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const block_interleaved_storage_scheme<index_type>& gko::preconditioner::Jacobi< ValueType,
IndexType >::get_storage_scheme ( ) const [inline], [noexcept]
```

Returns the storage scheme used for storing Jacobi blocks.

## Returns

the storage scheme used for storing Jacobi blocks

## 26.54.2.7 move\_to()

Converts the implementer to an object of type result\_type by moving data from this object.

This method is used when the implementer is a temporary object, and move semantics can be used.

#### **Parameters**

```
result the object used to emplace the result of the conversion
```

#### Note

Convertible To::move\_to can be implemented by simply calling Convertible To::convert\_to. However, this operation can often be optimized by exploiting the fact that implementer's data can be moved to the result.

Implements gko::ConvertibleTo< matrix::Dense< ValueType >>.

## 26.54.2.8 write()

Writes a matrix to a matrix\_data structure.

## **Parameters**

```
data the matrix_data structure
```

Implements gko::WritableToMatrixData< ValueType, IndexType >.

The documentation for this class was generated from the following file:

ginkgo/core/preconditioner/jacobi.hpp (638db8ca9)

## 26.55 gko::KernelNotFound Class Reference

KernelNotFound is thrown if Ginkgo cannot find a kernel which satisfies the criteria imposed by the input arguments.

```
#include <ginkgo/core/base/exception.hpp>
```

## **Public Member Functions**

KernelNotFound (const std::string &file, int line, const std::string &func)
 Initializes a KernelNotFound error.

## 26.55.1 Detailed Description

KernelNotFound is thrown if Ginkgo cannot find a kernel which satisfies the criteria imposed by the input arguments.

## 26.55.2 Constructor & Destructor Documentation

## 26.55.2.1 KernelNotFound()

Initializes a KernelNotFound error.

#### **Parameters**

file	The name of the offending source file
line	The source code line number where the error occurred
func	The name of the function where the error occurred

# 26.58 gko::LinOpFactory Class Reference

A LinOpFactory represents a higher order mapping which transforms one linear operator into another.

#include <ginkgo/core/base/lin\_op.hpp>

#### **Additional Inherited Members**

## 26.58.1 Detailed Description

A LinOpFactory represents a higher order mapping which transforms one linear operator into another.

In Ginkgo, every linear solver is viewed as a mapping. For example, given an s.p.d linear system Ax = b, the solution  $x = A^{-1}b$  can be computed using the CG method. This algorithm can be represented in terms of linear operators and mappings between them as follows:

- A Cg::Factory is a higher order mapping which, given an input operator A, returns a new linear operator  $A^{-1}$  stored in "CG format"
- Storing the operator  $A^{-1}$  in "CG format" means that the data structure used to store the operator is just a simple pointer to the original matrix A. The application  $x=A^{-1}b$  of such an operator can then be implemented by solving the linear system Ax=b using the CG method. This is achieved in code by having a special class for each of those "formats" (e.g. the "Cg" class defines such a format for the CG solver).

Another example of a LinOpFactory is a preconditioner. A preconditioner for a linear operator A is a linear operator  $M^{-1}$ , which approximates  $A^{-1}$ . In addition, it is stored in a way such that both the data of  $M^{-1}$  is cheap to compute from A, and the operation  $x = M^{-1}b$  can be computed quickly. These operators are useful to accelerate the convergence of Krylov solvers. Thus, a preconditioner also fits into the LinOpFactory framework:

- The factory maps a linear operator A into a preconditioner  $M^{-1}$  which is stored in suitable format (e.g. as a product of two factors in case of ILU preconditioners).
- The resulting linear operator implements the application operation  $x=M^{-1}b$  depending on the format the preconditioner is stored in (e.g. as two triangular solves in case of ILU)

#### 26.58.1.1 Example: using CG in Ginkgo

```
{c++}
// Suppose A is a matrix, b a rhs vector, and x an initial guess
// Create a CG which runs for at most 1000 iterations, and stops after
// reducing the residual norm by 6 orders of magnitude
auto cg_factory = solver::Cg<>::build()
    .with_max_iters(1000)
    .with_rel_residual_goal(1e-6)
    .on(cuda);
// create a linear operator which represents the solver
auto cg = cg_factory->generate(A);
// solve the system
cg->apply(gko::lend(b), gko::lend(x));
```

The documentation for this class was generated from the following file:

ginkgo/core/base/lin\_op.hpp (da7880906)

## 26.59 gko::log::Loggable Class Reference

Loggable class is an interface which should be implemented by classes wanting to support logging.

```
#include <ginkgo/core/log/logger.hpp>
```

#### **Public Member Functions**

virtual void add\_logger (std::shared\_ptr< const Logger > logger)=0

Adds a new logger to the list of subscribed loggers.

• virtual void remove\_logger (const Logger \*logger)=0

Removes a logger from the list of subscribed loggers.

## 26.59.1 Detailed Description

Loggable class is an interface which should be implemented by classes wanting to support logging.

For most cases, one can rely on the EnableLogging mixin which provides a default implementation of this interface.

## 26.59.2 Member Function Documentation

## 26.59.2.1 add\_logger()

Adds a new logger to the list of subscribed loggers.

## Parameters

logger	the logger to add

Implemented in gko::log::EnableLogging< ConcreteLoggable, PolymorphicBase >, gko::log::EnableLogging< PolymorphicObject >, and gko::log::EnableLogging< Executor >.

## 26.59.2.2 remove\_logger()

Removes a logger from the list of subscribed loggers.

## **Parameters**

logger	the logger to remove
--------	----------------------

Note

The comparison is done using the logger's object unique identity. Thus, two loggers constructed in the same way are not considered equal.

Implemented in gko::log::EnableLogging< ConcreteLoggable, PolymorphicBase >, gko::log::EnableLogging< PolymorphicObject >, and gko::log::EnableLogging< Executor >.

The documentation for this class was generated from the following file:

• ginkgo/core/log/logger.hpp (0d7578c92)

# 26.60 gko::log::Record::logged\_data Struct Reference

Struct storing the actually logged data.

#include <ginkgo/core/log/record.hpp>

## 26.60.1 Detailed Description

Struct storing the actually logged data.

The documentation for this struct was generated from the following file:

ginkgo/core/log/record.hpp (f0a50f96f)

# 26.61 gko::solver::LowerTrs< ValueType, IndexType > Class Template Reference

LowerTrs is the triangular solver which solves the system L x = b, when L is a lower triangular matrix.

#include <ginkgo/core/solver/lower\_trs.hpp>

## **Public Member Functions**

• std::shared\_ptr< const matrix::Csr< ValueType, IndexType > > get\_system\_matrix () const Gets the system operator (CSR matrix) of the linear system.

## 26.61.1 Detailed Description

template<typename ValueType = default\_precision, typename IndexType = int32> class gko::solver::LowerTrs< ValueType, IndexType >

LowerTrs is the triangular solver which solves the system L x = b, when L is a lower triangular matrix.

It works best when passing in a matrix in CSR format. If the matrix is not in CSR, then the generate step converts it into a CSR matrix. The generation fails if the matrix is not convertible to CSR.

Note

As the constructor uses the copy and convert functionality, it is not possible to create a empty solver or a solver with a matrix in any other format other than CSR, if none of the executor modules are being compiled with.

## **Template Parameters**

ValueType	precision of matrix elements
IndexType	precision of matrix indices

## 26.61.2 Member Function Documentation

## 26.61.2.1 get\_system\_matrix()

```
template<typename ValueType = default_precision, typename IndexType = int32>
std::shared_ptr<const matrix::Csr<ValueType, IndexType> > gko::solver::LowerTrs< ValueType,
IndexType>::get_system_matrix ( ) const [inline]
```

Gets the system operator (CSR matrix) of the linear system.

## Returns

the system operator (CSR matrix)

The documentation for this class was generated from the following file:

• ginkgo/core/solver/lower\_trs.hpp (faefed25b)

# 26.62 gko::matrix\_data< ValueType, IndexType > Struct Template Reference

This structure is used as an intermediate data type to store a sparse matrix.

```
#include <ginkgo/core/base/matrix_data.hpp>
```

## **Classes**

struct nonzero\_type

Type used to store nonzeros.

#### **Public Member Functions**

- matrix\_data (dim< 2 > size\_=dim< 2 >{}, ValueType value=zero< ValueType >())
- template < typename RandomDistribution, typename RandomEngine > matrix\_data (dim < 2 > size\_, RandomDistribution & dist, RandomEngine & engine)

Initializes a matrix with random values from the specified distribution.

matrix data (std::initializer list< std::initializer list< ValueType >> values)

List-initializes the structure from a matrix of values.

Initializes a matrix filled with the specified value.

matrix\_data (dim< 2 > size\_, std::initializer\_list< detail::input\_triple< ValueType, IndexType >> nonzeros
 —)

Initializes the structure from a list of nonzeros.

matrix\_data (dim< 2 > size\_, const matrix\_data &block)

Initializes a matrix out of a matrix block via duplication.

template<typename Accessor >

matrix\_data (const range< Accessor > &data)

Initializes a matrix from a range.

void ensure row major order ()

Sorts the nonzero vector so the values follow row-major order.

#### **Static Public Member Functions**

static matrix\_data diag (dim< 2 > size\_, ValueType value)

Initializes a diagonal matrix.

static matrix\_data diag (dim< 2 > size\_, std::initializer\_list< ValueType > nonzeros\_)

Initializes a diagonal matrix using a list of diagonal elements.

static matrix\_data diag (dim< 2 > size\_, const matrix\_data &block)

Initializes a block-diagonal matrix.

• template<typename ForwardIterator >

static matrix data diag (ForwardIterator begin, ForwardIterator end)

Initializes a block-diagonal matrix from a list of diagonal blocks.

static matrix\_data diag (std::initializer\_list< matrix\_data > blocks)

Initializes a block-diagonal matrix from a list of diagonal blocks.

template < typename RandomDistribution , typename RandomEngine >
 static matrix\_data cond (size\_type size, remove\_complex < ValueType > condition\_number, Random
 Distribution &&dist, RandomEngine &&engine, size\_type num\_reflectors)

Initializes a random dense matrix with a specific condition number.

template<typename RandomDistribution, typename RandomEngine >
 static matrix\_data cond (size\_type size, remove\_complex< ValueType > condition\_number, Random
 Distribution &&dist, RandomEngine &&engine)

Initializes a random dense matrix with a specific condition number.

## **Public Attributes**

dim< 2 > size

Size of the matrix.

std::vector< nonzero\_type > nonzeros

A vector of tuples storing the non-zeros of the matrix.

## 26.62.1 Detailed Description

template<typename ValueType = default\_precision, typename IndexType = int32> struct gko::matrix\_data< ValueType, IndexType >

This structure is used as an intermediate data type to store a sparse matrix.

The matrix is stored as a sequence of nonzero elements, where each element is a triple of the form (row\_index, column\_index, value).

#### Note

All Ginkgo functions returning such a structure will return the nonzeros sorted in row-major order.

All Ginkgo functions that take this structure as input expect that the nonzeros are sorted in row-major order.

This structure is not optimized for usual access patterns and it can only exist on the CPU. Thus, it should only be used for utility functions which do not have to be optimized for performance.

## **Template Parameters**

ValueType	type of matrix values stored in the structure
IndexType	type of matrix indexes stored in the structure

## 26.62.2 Constructor & Destructor Documentation

## 26.62.2.1 matrix data() [1/6]

Initializes a matrix filled with the specified value.

## **Parameters**

<i>size</i> ← –	dimensions of the matrix
value	value used to fill the elements of the matrix

```
{}, ValueType value = zero<ValueType>())
144
145
                  : size{size }
146
147
                  if (value == zero<ValueType>()) {
148
149
                  for (size_type row = 0; row < size[0]; ++row) {
   for (size_type col = 0; col < size[1]; ++col) {
      nonzeros.emplace_back(row, col, value);</pre>
150
151
152
153
154
155
```

## 26.62.2.2 matrix\_data() [2/6]

Initializes a matrix with random values from the specified distribution.

## **Template Parameters**

RandomDistribution	random distribution type
RandomEngine	random engine type

## **Parameters**

size⊷	dimensions of the matrix
dist	random distribution of the elements of the matrix
engine	random engine used to generate random values

## 26.62.2.3 matrix\_data() [3/6]

List-initializes the structure from a matrix of values.

#### **Parameters**

```
values a 2D braced-init-list of matrix values.
```

## 26.62.2.4 matrix\_data() [4/6]

Initializes the structure from a list of nonzeros.

#### **Parameters**

size_	dimensions of the matrix
nonzeros⊷	list of nonzero elements
_	

## 26.62.2.5 matrix\_data() [5/6]

Initializes a matrix out of a matrix block via duplication.

## **Parameters**

size	size of the block-matrix (in blocks)
diag_block	matrix block used to fill the complete matrix

References gko::matrix\_data< ValueType, IndexType >::size.

## 26.62.2.6 matrix\_data() [6/6]

Initializes a matrix from a range.

## **Template Parameters**

Accessor	accessor type of the input range
----------	----------------------------------

## **Parameters**

data	range used to initialize the matrix
------	-------------------------------------

References gko::range< Accessor >::length().

## 26.62.3 Member Function Documentation

## 26.62.3.1 cond() [1/2]

Initializes a random dense matrix with a specific condition number.

The matrix is generated by applying a series of random Hausholder reflectors to a diagonal matrix with diagonal entries uniformly distributed between sqrt (condition\_number) and 1/sqrt (condition\_number).

This version of the function applies size - 1 reflectors to each side of the diagonal matrix.

## **Template Parameters**

RandomDistribution	the type of the random distribution
RandomEngine	the type of the random engine

#### **Parameters**

size	number of rows and columns of the matrix
condition_number	condition number of the matrix
dist	random distribution used to generate reflectors
engine	random engine used to generate reflectors

## Returns

the dense matrix with the specified condition number

References gko::matrix\_data < ValueType, IndexType >::cond(), and gko::matrix\_data < ValueType, IndexType > \cdot ::size.

## 26.62.3.2 cond() [2/2]

Initializes a random dense matrix with a specific condition number.

The matrix is generated by applying a series of random Hausholder reflectors to a diagonal matrix with diagonal entries uniformly distributed between sqrt (condition\_number) and 1/sqrt (condition\_number).

## **Template Parameters**

RandomDistribution	the type of the random distribution
RandomEngine	the type of the random engine

## **Parameters**

size	number of rows and columns of the matrix
condition_number	condition number of the matrix
dist	random distribution used to generate reflectors
engine	random engine used to generate reflectors
num_reflectors	number of reflectors to apply from each side

## Returns

the dense matrix with the specified condition number

References gko::matrix\_data< ValueType, IndexType >::size.

Referenced by gko::matrix\_data < ValueType, IndexType >::cond().

## 26.62.3.3 diag() [1/5]

Initializes a block-diagonal matrix.

## **Parameters**

size_	the size of the matrix
diag_block	matrix used to fill diagonal blocks

#### Returns

the block-diagonal matrix

References gko::matrix\_data< ValueType, IndexType >::nonzeros, and gko::matrix\_data< ValueType, IndexType >::size.

## 26.62.3.4 diag() [2/5]

Initializes a diagonal matrix using a list of diagonal elements.

## **Parameters**

size_	dimensions of the matrix
nonzeros⊷	list of diagonal elements
_	

## Returns

the diagonal matrix

References gko::matrix\_data< ValueType, IndexType >::nonzeros.

#### 26.62.3.5 diag() [3/5]

Initializes a diagonal matrix.

#### **Parameters**

size⊷ –	dimensions of the matrix
value	value used to fill the elements of the matrix

#### Returns

the diagonal matrix

References gko::matrix\_data< ValueType, IndexType >::nonzeros.

Referenced by gko::matrix\_data< ValueType, IndexType >::diag().

## 26.62.3.6 diag() [4/5]

Initializes a block-diagonal matrix from a list of diagonal blocks.

## **Template Parameters**

ForwardIterator	type of list iterator
-----------------	-----------------------

#### **Parameters**

begin	the first iterator of the list
end	the last iterator of the list

#### Returns

the block-diagonal matrix with diagonal blocks set to the blocks between begin (inclusive) and end (exclusive)

References gko::matrix\_data< ValueType, IndexType >::nonzeros.

## 26.62.3.7 diag() [5/5]

Initializes a block-diagonal matrix from a list of diagonal blocks.

## **Parameters**

```
blocks a list of blocks to initialize from
```

## Returns

the block-diagonal matrix with diagonal blocks set to the blocks passed in blocks

References gko::matrix\_data< ValueType, IndexType >::diag().

## 26.62.4 Member Data Documentation

## 26.62.4.1 nonzeros

```
template<typename ValueType = default_precision, typename IndexType = int32>
std::vector<nonzero_type> gko::matrix_data< ValueType, IndexType >::nonzeros
```

A vector of tuples storing the non-zeros of the matrix.

The first two elements of the tuple are the row index and the column index of a matrix element, and its third element is the value at that position.

Referenced by gko::matrix\_data < ValueType, IndexType >::diag(), and gko::matrix\_data < ValueType, IndexType >::ensure\_row\_major\_order().

The documentation for this struct was generated from the following file:

• ginkgo/core/base/matrix\_data.hpp (ffa4bb4e4)

# 26.63 gko::matrix::Hybrid< ValueType, IndexType >::minimal\_storage\_limit Class Reference

minimal\_storage\_limit is a stratgy\_type which decides the number of stored elements per row of the ell part.

```
#include <ginkgo/core/matrix/hybrid.hpp>
```

#### **Public Member Functions**

- minimal\_storage\_limit ()
   Creates a minimal\_storage\_limit strategy.
- size\_type compute\_ell\_num\_stored\_elements\_per\_row (Array < size\_type > \*row\_nnz) const override
   Computes the number of stored elements per row of the ell part.

## 26.63.1 Detailed Description

```
template < typename ValueType = default_precision, typename IndexType = int32 > class gko::matrix::Hybrid < ValueType, IndexType >::minimal_storage_limit
```

minimal\_storage\_limit is a stratgy\_type which decides the number of stored elements per row of the ell part.

It is determined by the size of ValueType and IndexType, the storage is the minimum among all partition.

## 26.63.2 Member Function Documentation

#### 26.63.2.1 compute ell num stored elements per row()

```
template<typename ValueType = default_precision, typename IndexType = int32> size_type gko::matrix::Hybrid< ValueType, IndexType >::minimal_storage_limit::compute_ell_← num_stored_elements_per_row (

Array< size_type > * row_nnz ) const [inline], [override], [virtual]
```

Computes the number of stored elements per row of the ell part.

#### **Parameters**

row_nnz	the number of nonzeros of each row
---------	------------------------------------

#### Returns

the number of stored elements per row of the ell part

Implements gko::matrix::Hybrid< ValueType, IndexType >::strategy\_type.

References gko::matrix::Hybrid< ValueType, IndexType >::imbalance\_limit::compute\_ell\_num\_stored\_elements ← \_per\_row().

The documentation for this class was generated from the following file:

## 26.65 gko::NotCompiled Class Reference

NotCompiled is thrown when attempting to call an operation which is a part of a module that was not compiled on the system.

#include <ginkgo/core/base/exception.hpp>

## **Public Member Functions**

NotCompiled (const std::string &file, int line, const std::string &func, const std::string &module)
 Initializes a NotCompiled error.

## 26.65.1 Detailed Description

NotCompiled is thrown when attempting to call an operation which is a part of a module that was not compiled on the system.

## 26.65.2 Constructor & Destructor Documentation

## 26.65.2.1 NotCompiled()

Initializes a NotCompiled error.

#### **Parameters**

file	The name of the offending source file
line	The source code line number where the error occurred
func	The name of the function that has not been compiled
module	The name of the module which contains the function

The documentation for this class was generated from the following file:

• ginkgo/core/base/exception.hpp (6e8865457)

# 26.66 gko::NotImplemented Class Reference

NotImplemented is thrown in case an operation has not yet been implemented (but will be implemented in the future).

```
#include <ginkgo/core/base/exception.hpp>
```

## **Public Member Functions**

NotImplemented (const std::string &file, int line, const std::string &func)
 Initializes a NotImplemented error.

## 26.66.1 Detailed Description

NotImplemented is thrown in case an operation has not yet been implemented (but will be implemented in the future).

## 26.66.2 Constructor & Destructor Documentation

## 26.66.2.1 NotImplemented()

Initializes a NotImplemented error.

#### **Parameters**

file	The name of the offending source file
line	The source code line number where the error occurred
func	The name of the not-yet implemented function

The documentation for this class was generated from the following file:

• ginkgo/core/base/exception.hpp (6e8865457)

## 26.67 gko::NotSupported Class Reference

NotSupported is thrown in case it is not possible to perform the requested operation on the given object type.

```
#include <ginkgo/core/base/exception.hpp>
```

## **Public Member Functions**

NotSupported (const std::string &file, int line, const std::string &func, const std::string &obj\_type)
 Initializes a NotSupported error.

## 26.67.1 Detailed Description

NotSupported is thrown in case it is not possible to perform the requested operation on the given object type.

## 26.67.2 Constructor & Destructor Documentation

## 26.67.2.1 NotSupported()

Initializes a NotSupported error.

#### **Parameters**

file	The name of the offending source file
line	The source code line number where the error occurred
func	The name of the function where the error occured
obj_type	The object type on which the requested operation cannot be performed.

The documentation for this class was generated from the following file:

ginkgo/core/base/exception.hpp (6e8865457)

# 26.68 gko::null\_deleter< T > Class Template Reference

This is a deleter that does not delete the object.

```
#include <ginkgo/core/base/utils.hpp>
```

# **Public Member Functions**

void operator() (pointer) const noexcept
 Deletes the object.

# 26.68.1 Detailed Description

```
template < typename T > class gko::null_deleter < T >
```

This is a deleter that does not delete the object.

It is useful where the object has been allocated elsewhere and will be deleted manually.

#### 26.68.2 Member Function Documentation

## 26.68.2.1 operator()()

Deletes the object.

#### **Parameters**

ptr pointer to the object being deleted

The documentation for this class was generated from the following file:

# 26.69 gko::OmpExecutor Class Reference

This is the Executor subclass which represents the OpenMP device (typically CPU).

#include <ginkgo/core/base/executor.hpp>

## **Public Member Functions**

- std::shared\_ptr< Executor > get\_master () noexcept override
   Returns the master OmpExecutor of this Executor.
- std::shared\_ptr< const Executor > get\_master () const noexcept override

  \*Returns the master OmpExecutor of this Executor.
- · void synchronize () const override

Synchronize the operations launched on the executor with its master.

#### **Static Public Member Functions**

static std::shared\_ptr< OmpExecutor > create ()
 Creates a new OmpExecutor.

# 26.69.1 Detailed Description

This is the Executor subclass which represents the OpenMP device (typically CPU).

## 26.69.2 Member Function Documentation

## 26.69.2.1 get\_master() [1/2]

std::shared\_ptr<const Executor> gko::OmpExecutor::get\_master ( ) const [override], [virtual],
[noexcept]

Returns the master OmpExecutor of this Executor.

#### Returns

the master OmpExecutor of this Executor.

Implements gko::Executor.

#### 26.69.2.2 get\_master() [2/2]

```
std::shared_ptr<Executor> gko::OmpExecutor::get_master ( ) [override], [virtual], [noexcept]
```

Returns the master OmpExecutor of this Executor.

Returns

the master OmpExecutor of this Executor.

Implements gko::Executor.

The documentation for this class was generated from the following file:

ginkgo/core/base/executor.hpp (8f70a7c81)

# 26.70 gko::Operation Class Reference

Operations can be used to define functionalities whose implementations differ among devices.

```
#include <ginkgo/core/base/executor.hpp>
```

#### **Public Member Functions**

 virtual const char \* get\_name () const noexcept
 Returns the operation's name.

#### 26.70.1 Detailed Description

Operations can be used to define functionalities whose implementations differ among devices.

This is done by extending the Operation class and implementing the overloads of the Operation::run() method for all Executor types. When invoking the Executor::run() method with the Operation as input, the library will select the Operation::run() overload corresponding to the dynamic type of the Executor instance.

Consider an overload of operator << for Executors, which prints some basic device information (e.g. device type and id) of the Executor to a C++ stream:

```
std::ostream& operator (std::ostream &os, const gko::Executor &exec);
```

One possible implementation would be to use RTTI to find the dynamic type of the Executor, However, using the Operation feature of Ginkgo, there is a more elegant approach which utilizes polymorphism. The first step is to define an Operation that will print the desired information for each Executor type.

```
class DeviceInfoPrinter : public gko::Operation {
public:
    explicit DeviceInfoPrinter(std::ostream &os) : os_(os) {}
    void run(const gko::OmpExecutor *) const override { os_ « "OMP"; }
    void run(const gko::CudaExecutor *exec) const override
    { os_ « "CUDA(" « exec->get_device_id() « ")"; }
    // This is optional, if not overloaded, defaults to OmpExecutor overload
    void run(const gko::ReferenceExecutor *) const override
    { os_ « "Reference CPU"; }
private:
    std::ostream &os_;
};
```

Using DeviceInfoPrinter, the implementation of operator << is as simple as calling the run() method of the executor.

```
std::ostream& operator«(std::ostream &os, const gko::Executor &exec)
{
    DeviceInfoPrinter printer(os);
    exec.run(printer);
    return os;
}
```

Now it is possible to write the following code:

which produces the expected output:

```
OMP
CUDA(0)
Reference CPU
```

One might feel that this code is too complicated for such a simple task. Luckily, there is an overload of the Executor::run() method, which is designed to facilitate writing simple operations like this one. The method takes two closures as input: one which is run for OMP, and the other one for CUDA executors. Using this method, there is no need to implement an Operation subclass:

Using this approach, however, it is impossible to distinguish between a OmpExecutor and ReferenceExecutor, as both of them call the OMP closure.

#### 26.70.2 Member Function Documentation

#### 26.70.2.1 get name()

```
virtual const char* gko::Operation::get_name ( ) const [virtual], [noexcept]
```

Returns the operation's name.

Returns

the operation's name

OutOfBoundsError is thrown if a memory access is detected to be out-of-bounds.

# 26.72.2 Constructor & Destructor Documentation

# 26.72.2.1 OutOfBoundsError()

Initializes an OutOfBoundsError.

#### **Parameters**

file	The name of the offending source file
line	The source code line number where the error occurred
index	The position that was accessed
bound	The first out-of-bound index

The documentation for this class was generated from the following file:

• ginkgo/core/base/exception.hpp (6e8865457)

# 26.73 gko::factorization::Parllu< ValueType, IndexType > Class Template Reference

ParILU is an incomplete LU factorization which is computed in parallel.

#include <ginkgo/core/factorization/par\_ilu.hpp>

#### **Additional Inherited Members**

## 26.73.1 Detailed Description

template<typename ValueType = default\_precision, typename IndexType = int32> class gko::factorization::Parllu< ValueType, IndexType >

ParILU is an incomplete LU factorization which is computed in parallel.

L is a lower unitriangular, while U is an upper triangular matrix, which approximate a given matrix A with  $A \approx LU$ . Here, L and U have the same sparsity pattern as A, which is also called ILU(0).

The ParILU algorithm generates the incomplete factors iteratively, using a fixed-point iteration of the form

$$F(L,U) = \begin{cases} \frac{1}{u_{jj}} \left( a_{ij} - \sum_{k=1}^{j-1} l_{ik} u_{kj} \right), & i > j \\ a_{ij} - \sum_{k=1}^{j-1} l_{ik} u_{kj}, & i \leq j \end{cases}$$

In general, the entries of L and U can be iterated in parallel and in asynchronous fashion, the algorithm asymptotically converges to the incomplete factors L and U fulfilling  $(R = A - L \cdot U) \mid_{\mathcal{S}} = 0 \mid_{\mathcal{S}}$  where  $\mathcal{S}$  is the pre-defined sparsity pattern (in case of ILU(0) the sparsity pattern of the system matrix A). The number of ParILU sweeps needed for convergence depends on the parallelism level: For sequential execution, a single sweep is sufficient, for fine-grained parallelism, 3 sweeps are typically generating a good approximation.

The ParlLU algorithm in Ginkgo follows the design of E. Chow and A. Patel, Fine-grained Parallel Incomplete LU Factorization, SIAM Journal on Scientific Computing, 37, C169-C193 (2015).

#### **Template Parameters**

ValueType	Type of the values of all matrices used in this class
IndexType	Type of the indices of all matrices used in this class

The documentation for this class was generated from the following file:

• ginkgo/core/factorization/par ilu.hpp (a78f5f7a1)

# 26.74 gko::Perturbation < ValueType > Class Template Reference

The Perturbation class can be used to construct a LinOp to represent the operation (identity + scalar \* basis \* projector).

#include <ginkgo/core/base/perturbation.hpp>

#### **Public Member Functions**

- const std::shared\_ptr< const LinOp > get\_basis () const noexcept

  Returns the basis of the perturbation.
- const std::shared\_ptr< const LinOp > get\_projector () const noexcept

  Returns the projector of the perturbation.
- const std::shared\_ptr< const LinOp > get\_scalar () const noexcept

  Returns the scalar of the perturbation.

## 26.74.1 Detailed Description

```
template < typename ValueType = default_precision > class gko::Perturbation < ValueType >
```

The Perturbation class can be used to construct a LinOp to represent the operation (identity + scalar \* basis \* projector).

This operator adds a movement along a direction constructed by basis and projector on the LinOp. projector gives the coefficient of basis to decide the direction.

For example, the Householder matrix can be represented with the Perturbation operator as follows. If u is the Householder factor then we can generate the Householder transformation, H = (I - 2 u u\*). In this case, the parameters of Perturbation class are scalar = -2, basis = u, and projector = u\*.

#### **Template Parameters**

ValueType	precision of input and result vectors
-----------	---------------------------------------

Note

the apply operations of Perturbation class are not thread safe

## 26.74.2 Member Function Documentation

#### 26.74.2.1 get\_basis()

```
template<typename ValueType = default_precision>
const std::shared_ptr<const LinOp> gko::Perturbation< ValueType >::get_basis ( ) const [inline],
[noexcept]
```

Returns the basis of the perturbation.

#### Returns

# the basis of the perturbation

```
81 {
82     return basis_;
83 }
```

## 26.74.2.2 get\_projector()

```
template<typename ValueType = default_precision>
const std::shared_ptr<const LinOp> gko::Perturbation< ValueType >::get_projector ( ) const
[inline], [noexcept]
```

Returns the projector of the perturbation.

Returns

the projector of the perturbation

# 26.74.2.3 get\_scalar()

```
template<typename ValueType = default_precision>
const std::shared_ptr<const LinOp> gko::Perturbation< ValueType >::get_scalar ( ) const [inline],
[noexcept]
```

Returns the scalar of the perturbation.

Returns

the scalar of the perturbation

```

# 26.75.1 Detailed Description

Struct representing PolymorphicObject related data.

The documentation for this struct was generated from the following file:

ginkgo/core/log/record.hpp (f0a50f96f)

# 26.76 gko::PolymorphicObject Class Reference

A PolymorphicObject is the abstract base for all "heavy" objects in Ginkgo that behave polymorphically.

#include <ginkgo/core/base/polymorphic\_object.hpp>

#### **Public Member Functions**

- std::unique\_ptr< PolymorphicObject > create\_default (std::shared\_ptr< const Executor > exec) const Creates a new "default" object of the same dynamic type as this object.
- std::unique\_ptr< PolymorphicObject > create\_default () const

Creates a new "default" object of the same dynamic type as this object.

- std::unique\_ptr< PolymorphicObject > clone (std::shared\_ptr< const Executor > exec) const
   Creates a clone of the object.
- std::unique\_ptr< PolymorphicObject > clone () const

Creates a clone of the object.

PolymorphicObject \* copy\_from (const PolymorphicObject \*other)

Copies another object into this object.

PolymorphicObject \* copy from (std::unique ptr< PolymorphicObject > other)

Moves another object into this object.

PolymorphicObject \* clear ()

Transforms the object into its default state.

std::shared\_ptr< const Executor > get\_executor () const noexcept

Returns the Executor of the object.

## 26.76.1 Detailed Description

A PolymorphicObject is the abstract base for all "heavy" objects in Ginkgo that behave polymorphically.

It defines the basic utilities (copying moving, cloning, clearing the objects) for all such objects. It takes into account that these objects are dynamically allocated, managed by smart pointers, and used polymorphically. Additionally, it assumes their data can be allocated on different executors, and that they can be copied between those executors.

#### Note

Most of the public methods of this class should not be overridden directly, and are thus not virtual. Instead, there are equivalent protected methods (ending in <method\_name>\_impl) that should be overriden instead. This allows polymorphic objects to implement default behavior around virtual methods (parameter checking, type casting).

## See also

EnablePolymorphicObject if you wish to implement a concrete polymorphic object and have sensible defaults generated automatically. EnableAbstractPolymorphicObject if you wish to implement a new abstract polymorphic object, and have the return types of the methods updated to your type (instead of having them return PolymorphicObject).

#### 26.76.2 Member Function Documentation

#### 26.76.2.1 clear()

```
PolymorphicObject* gko::PolymorphicObject::clear ( ) [inline]
```

Transforms the object into its default state.

Equivalent to this->copy\_from(this->create\_default()).

See also

clear\_impl() when implementing this method

Returns

this

# 26.76.2.2 clone() [1/2]

```
std::unique_ptr<PolymorphicObject> gko::PolymorphicObject::clone ( ) const [inline]
```

Creates a clone of the object.

This is a shorthand for clone(std::shared\_ptr<const Executor>) that uses the executor of this object to construct the new object.

Returns

A clone of the LinOp.

## 26.76.2.3 clone() [2/2]

Creates a clone of the object.

This is the polymorphic equivalent of the executor copy constructor decltype (\*this) (exec, this).

## **Parameters**

*exec* the executor where the clone will be created

#### Returns

A clone of the LinOp.

References create\_default().

# 26.76.2.4 copy\_from() [1/2]

Copies another object into this object.

This is the polymorphic equivalent of the copy assignment operator.

## See also

```
copy_from_impl(const PolymorphicObject *)
```

#### **Parameters**

```
other the object to copy
```

#### Returns

this

#### 26.76.2.5 copy\_from() [2/2]

Moves another object into this object.

This is the polymorphic equivalent of the move assignment operator.

See also

```
copy_from_impl(std::unique_ptr<PolymorphicObject>)
```

#### **Parameters**

other	the object to move from
Olliel	line object to move nom

## Returns

this

### 26.76.2.6 create\_default() [1/2]

```
std::unique_ptr<PolymorphicObject> gko::PolymorphicObject::create_default ( ) const [inline]
```

Creates a new "default" object of the same dynamic type as this object.

This is a shorthand for create\_default(std::shared\_ptr<const Executor>) that uses the executor of this object to construct the new object.

#### Returns

a polymorphic object of the same type as this

Referenced by clone().

#### 26.76.2.7 create\_default() [2/2]

Creates a new "default" object of the same dynamic type as this object.

This is the polymorphic equivalent of the executor default constructor decltype (\*this) (exec);.

#### **Parameters**

```
exec the executor where the object will be created
```

#### Returns

a polymorphic object of the same type as this

#### 26.76.2.8 get\_executor()

```
std::shared_ptr<const Executor> gko::PolymorphicObject::get_executor ( ) const [inline],
[noexcept]
```

Returns the Executor of the object.

#### Returns

Executor of the object

Referenced by gko::matrix::Dense< ValueType >::add\_scaled(), gko::matrix::Coo< ValueType, IndexType > $\leftarrow$  ::apply2(), gko::matrix::Dense< ValueType >::compute\_dot(), gko::matrix::Dense< ValueType >::compute\_ $\leftarrow$  norm2(), gko::matrix::Dense< ValueType >::scale().

• ginkgo/core/base/polymorphic\_object.hpp (8f70a7c81)

# 26.77 gko::precision reduction Class Reference

This class is used to encode storage precisions of low precision algorithms.

#include <ginkgo/core/base/types.hpp>

## **Public Types**

• using storage\_type = uint8

The underlying datatype used to store the encoding.

#### **Public Member Functions**

· constexpr precision\_reduction () noexcept

Creates a default precision\_reduction encoding.

constexpr precision\_reduction (storage\_type preserving, storage\_type nonpreserving) noexcept

Creates a precision\_reduction encoding with the specified number of conversions.

• constexpr operator storage\_type () const noexcept

Extracts the raw data of the encoding.

constexpr storage\_type get\_preserving () const noexcept

Returns the number of preserving conversions in the encoding.

constexpr storage\_type get\_nonpreserving () const noexcept

Returns the number of non-preserving conversions in the encoding.

#### Static Public Member Functions

· constexpr static precision\_reduction autodetect () noexcept

Returns a special encoding which instructs the algorithm to automatically detect the best precision.

• constexpr static precision\_reduction common (precision\_reduction x, precision\_reduction y) noexcept

Returns the common encoding of input encodings.

## 26.77.1 Detailed Description

This class is used to encode storage precisions of low precision algorithms.

Some algorithms in Ginkgo can improve their performance by storing parts of the data in lower precision, while doing computation in full precision. This class is used to encode the precisions used to store the data. From the user's perspective, some algorithms can provide a parameter for fine-tuning the storage precision. Commonly, the special value returned by precision\_reduction::autodetect() should be used to allow the algorithm to automatically choose an appropriate value, though manually selected values can be used for fine-tuning.

In general, a lower precision floating point value can be obtained by either dropping some of the insignificant bits of the significand (keeping the same number of exponent bits, and thus preserving the range of representable values) or using one of the hardware or software supported conversions between IEEE formats, such as double to float or float to half (reducing both the number of exponent, as well as significand bits, and thus decreasing the range of representable values).

The precision\_reduction class encodes the lower precision format relative to the base precision used and the algorithm in question. The encoding is done by specifying the amount of range non-preserving conversions and

the amount of range preserving conversions that should be done on the base precision to obtain the lower precision format. For example, starting with a double precision value (11 exp, 52 sig. bits), the encoding specifying 1 non-preserving conversion and 1 preserving conversion would first use a hardware-supported non-preserving conversion to obtain a single precision value (8 exp, 23 sig. bits), followed by a preserving bit truncation to obtain a value with 8 exponent and 7 significand bits. Note that non-preserving conversion are always done first, as preserving conversions usually result in datatypes that are not supported by builtin conversions (thus, it is generally not possible to apply a non-preserving conversion to the result of a preserving conversion).

If the specified conversion is not supported by the algorithm, it will most likely fall back to using full precision for storing the data. Refer to the documentation of specific algorithms using this class for details about such special cases.

#### 26.77.2 Constructor & Destructor Documentation

#### 26.77.2.1 precision\_reduction() [1/2]

```
constexpr gko::precision_reduction::precision_reduction ( ) [inline], [constexpr], [noexcept]
```

Creates a default precision reduction encoding.

This encoding represents the case where no conversions are performed.

Referenced by common().

#### 26.77.2.2 precision\_reduction() [2/2]

Creates a precision\_reduction encoding with the specified number of conversions.

#### **Parameters**

preserving	the number of range preserving conversion
nonpreserving	the number of range non-preserving conversions

# 26.77.3 Member Function Documentation

#### 26.77.3.1 autodetect()

```
constexpr static precision_reduction gko::precision_reduction::autodetect ( ) [inline], [static],
[constexpr], [noexcept]
```

Returns a special encoding which instructs the algorithm to automatically detect the best precision.

#### Returns

a special encoding instructing the algorithm to automatically detect the best precision.

## 26.77.3.2 common()

Returns the common encoding of input encodings.

The common encoding is defined as the encoding that does not have more preserving, nor non-preserving conversions than the input encodings.

#### **Parameters**

X	an encoding
У	an encoding

#### Returns

the common encoding of  $\boldsymbol{x}$  and  $\boldsymbol{y}$ 

References precision\_reduction().

# 26.77.3.3 get\_nonpreserving()

```
constexpr storage_type gko::precision_reduction::get_nonpreserving ( ) const [inline], [constexpr],
[noexcept]
```

Returns the number of non-preserving conversions in the encoding.

## Returns

the number of non-preserving conversions in the encoding.

## 26.77.3.4 get\_preserving()

```
constexpr storage_type gko::precision_reduction::get_preserving ( ) const [inline], [constexpr],
[noexcept]
```

Returns the number of preserving conversions in the encoding.

#### Returns

the number of preserving conversions in the encoding.

## 26.77.3.5 operator storage\_type()

```
constexpr gko::precision_reduction::operator storage_type ( ) const [inline], [constexpr],
[noexcept]
```

Extracts the raw data of the encoding.

#### Returns

the raw data of the encoding

• ginkgo/core/base/types.hpp (d9817e348)

# 26.78 gko::Preconditionable Class Reference

A LinOp implementing this interface can be preconditioned.

```
#include <ginkgo/core/base/lin_op.hpp>
```

#### **Public Member Functions**

- virtual std::shared\_ptr< const LinOp > get\_preconditioner () const
   Returns the preconditioner operator used by the Preconditionable.
- virtual void set\_preconditioner (std::shared\_ptr< const LinOp > new\_precond)
   Sets the preconditioner operator used by the Preconditionable.

# 26.78.1 Detailed Description

A LinOp implementing this interface can be preconditioned.

#### 26.78.2 Member Function Documentation

#### 26.78.2.1 get preconditioner()

```
virtual std::shared_ptr<const LinOp> gko::Preconditionable::get_preconditioner ( ) const
[inline], [virtual]
```

Returns the preconditioner operator used by the Preconditionable.

#### Returns

the preconditioner operator used by the Preconditionable

# 26.78.2.2 set\_preconditioner()

Sets the preconditioner operator used by the Preconditionable.

#### **Parameters**

new\_precond the new preconditioner operator used by the Preconditionable

The documentation for this class was generated from the following file:

• ginkgo/core/base/lin\_op.hpp (da7880906)

# 26.79 gko::range< Accessor > Class Template Reference

A range is a multidimensional view of the memory.

```
#include <ginkgo/core/base/range.hpp>
```

# **Public Types**

• using accessor = Accessor

The type of the underlying accessor.

#### **Public Member Functions**

~range ()=default

Use the default destructor.

template < typename... AccessorParams >
 constexpr range (AccessorParams & & ... params)

Creates a new range.

template<typename... DimensionTypes>
 constexpr auto operator() (DimensionTypes &&... dimensions) const -> decltype(std::declval< accessor >()(std::forward< DimensionTypes >(dimensions)...))

Returns a value (or a sub-range) with the specified indexes.

template<typename OtherAccessor >
 const range & operator= (const range< OtherAccessor > &other) const

• const range & operator= (const range &other) const

Assigns another range to this range.

constexpr size\_type length (size\_type dimension) const

Returns the length of the specified dimension of the range.

constexpr const accessor \* operator-> () const noexcept

Returns a pointer to the accessor.

constexpr const accessor & get\_accessor () const noexcept

`Returns a reference to the accessor.

## **Static Public Attributes**

static constexpr size\_type dimensionality = accessor::dimensionality
 The number of dimensions of the range.

## 26.79.1 Detailed Description

```
template<typename Accessor> class gko::range< Accessor >
```

A range is a multidimensional view of the memory.

The range does not store any of its values by itself. Instead, it obtains the values through an accessor (e.g. accessor::row\_major) which describes how the indexes of the range map to physical locations in memory.

There are several advantages of using ranges instead of plain memory pointers:

- 1. Code using ranges is easier to read and write, as there is no need for index linearizations.
- Code using ranges is safer, as it is impossible to accidentally miscalculate an index or step out of bounds, since range accessors perform bounds checking in debug builds. For performance, this can be disabled in release builds by defining the NDEBUG flag.
- 3. Ranges enable generalized code, as algorithms can be written independent of the memory layout. This does not impede various optimizations based on memory layout, as it is always possible to specialize algorithms for ranges with specific memory layouts.
- 4. Ranges have various pointwise operations predefined, which reduces the amount of loops that need to be written.

#### 26.79.1.1 Range operations

Ranges define a complete set of pointwise unary and binary operators which extend the basic arithmetic operators in C++, as well as a few pointwise operations and mathematical functions useful in ginkgo, and a couple of non-pointwise operations. Compound assignment (+=, \*=, etc.) is not yet supported at this moment. Here is a complete list of operations:

- standard unary operations:  $+, -, !, \sim$
- standard binary operations: +, \* (this is pointwise, not matrix multiplication), /, %, <, >, <=, >=, ==, !=, ||, & &, |, &, ^, <<, >>
- useful unary functions: zero, one, abs, real, imag, conj, squared\_norm
- useful binary functions: min, max

All binary pointwise operations also work as expected if one of the operands is a scalar and the other is a range. The scalar operand will have the effect as if it was a range of the same size as the other operand, filled with the specified scalar.

Two "global" functions transpose and mmul are also supported. transpose transposes the first two dimensions of the range (i.e. transpose (r) (i, j, ...) == r(j, i, ...)). mmul performs a (batched) matrix multiply of the ranges - the first two dimensions represent the matrices, while the rest represent the batch. For example, given the ranges r1 and r2 of dimensions (3, 2, 3) and (2, 4, 3), respectively, mmul (r1, r2) will return a range of dimensions (3, 4, 3), obtained by multiplying the 3 frontal slices of the range, and stacking the result back vertically.

#### 26.79.1.2 Compound operations

Multiple range operations can be combined into a single expression. For example, an "axpy" operation can be obtained using y = alpha \* x + y, where x an y are ranges, and alpha is a scalar. Range operations are optimized for memory access, and the above code does not allocate additional storage for intermediate ranges alpha \* x or aplha \* x + y. In fact, the entire computation is done during the assignment, and the results of operations + and \* only register the data, and the types of operations that will be computed once the results are needed.

It is possible to store and reuse these intermediate expressions. The following example will overwrite the range  $\mathbf{x}$  with it's 4th power:

```
{c++} auto square = x * x; // this is range constructor, not range assignment! x = \text{square}; // overwrites x * \text{with } x * \text{wi
```

## 26.79.1.3 Caveats

\_\_mmul is not a highly-optimized BLAS-3 version of the matrix multiplication.\_\_ The current design of ranges and accessors prevents that, so if you need a high-perfromance matrix multiplication, you should use one of the libraries that provide that, or implement your own (you can use pointwise range operations to help simplify that). However, range design might get improved in the future to allow efficient implementations of BLAS-3 kernels.

Aliasing the result range in mmul and transpose is not allowed. Constructs like A = transpose(A), A = mmul(A, A), or A = mmul(A, A) + C lead to undefined behavior. However, aliasing input arguments is allowed: C = mmul(A, A), and even C = mmul(A, A) + C is valid code (in the last example, only pointwise operations are aliased). C = mmul(A, A + C) is not valid though.

#### 26.79.1.4 Examples

The range unit tests in core/test/base/range.cpp contain lots of simple 1-line examples of range operations. The accessor unit tests in core/test/base/range.cpp show how to use ranges with concrete accessors, and how to use range slices using spans as arguments to range function call operator. Finally, examples/range contains a complete example where ranges are used to implement a simple version of the right-looking LU factorization.

#### **Template Parameters**

underlying accessor of the range	Accessor
----------------------------------	----------

# 26.79.2 Constructor & Destructor Documentation

#### 26.79.2.1 range()

Creates a new range.

## **Template Parameters**

#### **Parameters**

params	parameters forwarded to Accessor constructor.

```
323 : accessor_{std::forward<AccessorParams>(params)...}
324 {}
```

# 26.79.3 Member Function Documentation

#### 26.79.3.1 get\_accessor()

```
template<typename Accessor>
constexpr const accessor& gko::range< Accessor >::get_accessor ( ) const [inline], [constexpr],
[noexcept]
```

`Returns a reference to the accessor.

#### Returns

reference to the accessor

Referenced by gko::range < Accessor >::operator=().

## 26.79.3.2 length()

Returns the length of the specified dimension of the range.

#### **Parameters**

ſ
---

#### Returns

the length of the dimension-th dimension of the range

Referenced by gko::matrix\_data< ValueType, IndexType >::matrix\_data().

## 26.79.3.3 operator()()

Returns a value (or a sub-range) with the specified indexes.

## **Template Parameters**

DimensionTypes	The types of indexes. Supported types depend on the underlying accessor, but are usually
	either integer types or spans. If at least one index is a span, the returned value will be a
	sub-range.

#### **Parameters**

dimoncione	the indexes of the values.
dimensions	ine indexes of the values.

#### Returns

```
a value on position (dimensions...).
```

References gko::range < Accessor >::dimensionality.

#### 26.79.3.4 operator->()

```
template<typename Accessor>
constexpr const accessor* gko::range< Accessor >::operator-> ( ) const [inline], [constexpr],
[noexcept]
```

Returns a pointer to the accessor.

Can be used to access data and functions of a specific accessor.

#### Returns

pointer to the accessor

#### 26.79.3.5 operator=() [1/2]

Assigns another range to this range.

The order of assignment is defined by the accessor of this range, thus the memory access will be optimized for the resulting range, and not for the other range. If the sizes of two ranges do not match, the result is undefined. Sizes of the ranges are checked at runtime in debug builds.

Note

Temporary accessors are allowed to define the implementation of the assignment as deleted, so do not expect r1 \* r2 = r2 to work.

#### **Parameters**

```
other the range to copy the data from
```

References gko::range < Accessor >::get\_accessor().

# 26.79.3.6 operator=() [2/2]

This is a version of the function which allows to copy between ranges of different accessors.

#### **Template Parameters**

OtherAccessor access	or of the other range
----------------------	-----------------------

The documentation for this class was generated from the following file:

• ginkgo/core/base/range.hpp (8f70a7c81)

# 26.80 gko::ReadableFromMatrixData< ValueType, IndexType > Class Template Reference

A LinOp implementing this interface can read its data from a matrix\_data structure.

```
#include <ginkgo/core/base/lin_op.hpp>
```

#### **Public Member Functions**

virtual void read (const matrix\_data < ValueType, IndexType > &data)=0
 Reads a matrix from a matrix\_data structure.

# 26.80.1 Detailed Description

```
template<typename ValueType, typename IndexType> class gko::ReadableFromMatrixData< ValueType, IndexType >
```

A LinOp implementing this interface can read its data from a matrix\_data structure.

#### 26.80.2 Member Function Documentation

#### 26.80.2.1 read()

Reads a matrix from a matrix\_data structure.

# **Parameters**

data	the matrix_data structure
------	---------------------------

Implemented in gko::matrix::Csr< ValueType, IndexType >, gko::matrix::Hybrid< ValueType, IndexType >, gko::matrix::Coo< ValueType, IndexType >, gko::matrix::Sellp< ValueType, IndexType >, and gko::matrix::SparsityCsr< ValueType, IndexType >.

# 26.81 gko::log::Record Class Reference

Record is a Logger which logs every event to an object.

```
#include <ginkgo/core/log/record.hpp>
```

#### **Classes**

· struct logged\_data

Struct storing the actually logged data.

#### **Public Member Functions**

- const logged\_data & get () const noexcept
   Returns the logged data.
- · logged\_data & get () noexcept

#### **Static Public Member Functions**

 static std::unique\_ptr< Record > create (std::shared\_ptr< const Executor > exec, const mask\_type &enabled\_events=Logger::all\_events\_mask, size\_type max\_storage=1)

Creates a Record logger.

# 26.81.1 Detailed Description

Record is a Logger which logs every event to an object.

The object can then be accessed at any time by asking the logger to return it.

Note

Please note that this logger can have significant memory and performance overhead. In particular, when logging events such as the <code>check</code> events, all parameters are cloned. If it is sufficient to clone one parameter, consider implementing a specific logger for this. In addition, it is advised to tune the history size in order to control memory overhead.

## 26.81.2 Member Function Documentation

## 26.81.2.1 create()

Creates a Record logger.

This dynamically allocates the memory, constructs the object and returns an std::unique\_ptr to this object.

#### **Parameters**

exec	the executor	
enabled_events	the events enabled for this logger. By default all events.	
max_storage	the size of storage (i.e. history) wanted by the user. By default 0 is used, which means unlimited storage. It is advised to control this to reduce memory overhead of this logger.	

#### Returns

an std::unique\_ptr to the the constructed object

#### 26.81.2.2 get() [1/2]

```
const logged_data& gko::log::Record::get ( ) const [inline], [noexcept]
```

Returns the logged data.

#### Returns

the logged data

## **26.81.2.3 get()** [2/2]

```
logged_data& gko::log::Record::get ( ) [inline], [noexcept]
```

# 26.82 gko::ReferenceExecutor Class Reference

This is a specialization of the OmpExecutor, which runs the reference implementations of the kernels used for debugging purposes.

```
#include <ginkgo/core/base/executor.hpp>
```

## **Public Member Functions**

void run (const Operation &op) const override
 Runs the specified Operation using this Executor.

#### **Additional Inherited Members**

# 26.82.1 Detailed Description

This is a specialization of the OmpExecutor, which runs the reference implementations of the kernels used for debugging purposes.

#### 26.82.2 Member Function Documentation

## 26.82.2.1 run()

Runs the specified Operation using this Executor.

#### **Parameters**

```
op the operation to run
```

Implements gko::Executor.

The documentation for this class was generated from the following file:

• ginkgo/core/base/executor.hpp (8f70a7c81)

# 26.83 gko::stop::ResidualNormReduction< ValueType > Class Template Reference

The ResidualNormReduction class is a stopping criterion which stops the iteration process when the relative residual norm is below a certain threshold.

```
#include <ginkgo/core/stop/residual_norm_reduction.hpp>
```

# 26.83.1 Detailed Description

```
template<typename ValueType = default_precision>
class gko::stop::ResidualNormReduction< ValueType >
```

The ResidualNormReduction class is a stopping criterion which stops the iteration process when the relative residual norm is below a certain threshold.

For better performance, the checks are run thanks to kernels on the executor where the algorithm is executed.

Note

To use this stopping criterion there are some dependencies. The constructor depends on <code>initial\_constitution residual</code> in order to compute the first relative residual norm. The check method depends on either the <code>residual\_norm</code> or the <code>residual being set</code>. When any of those is not correctly provided, an exception <code>::gko::NotSupported()</code> is thrown.

The documentation for this class was generated from the following file:

• ginkgo/core/stop/residual\_norm\_reduction.hpp (638db8ca9)

# 26.84 gko::accessor::row\_major< ValueType, Dimensionality > Class Template Reference

A row\_major accessor is a bridge between a range and the row-major memory layout.

#include <ginkgo/core/base/range\_accessors.hpp>

# **Public Types**

• using value\_type = ValueType

Type of values returned by the accessor.

using data\_type = value\_type \*

Type of underlying data storage.

## **Public Member Functions**

constexpr value\_type & operator() (size\_type row, size\_type col) const

Returns the data element at position (row, col)

• constexpr range < row\_major > operator() (const span &rows, const span &cols) const

Returns the sub-range spanning the range (rows, cols)

• constexpr size\_type length (size\_type dimension) const

Returns the length in dimension dimension.

template<typename OtherAccessor >

void copy\_from (const OtherAccessor &other) const

Copies data from another accessor.

#### **Public Attributes**

const data type data

Reference to the underlying data.

const std::array< const size\_type, dimensionality > lengths

An array of dimension sizes.

· const size\_type stride

Distance between consecutive rows.

#### **Static Public Attributes**

static constexpr size\_type dimensionality = 2
 Number of dimensions of the accessor.

# 26.84.1 Detailed Description

```
template<typename ValueType, size_type Dimensionality> class gko::accessor::row_major< ValueType, Dimensionality >
```

A row\_major accessor is a bridge between a range and the row-major memory layout.

You should never try to explicitly create an instance of this accessor. Instead, supply it as a template parameter to a range, and pass the constructor parameters for this class to the range (it will forward it to this class).

#### Warning

The current implementation is incomplete, and only allows for 2-dimensional ranges.

#### **Template Parameters**

ValueType	type of values this accessor returns
Dimensionality	number of dimensions of this accessor (has to be 2)

# 26.84.2 Member Function Documentation

## 26.84.2.1 copy\_from()

Copies data from another accessor.

## **Template Parameters**

OtherAccessor	type of the other accessor
---------------	----------------------------

#### **Parameters**

other	other accessor	
164	{	
165 166		e i = 0; i < lengths[0]; ++i) { _type j = 0; j < lengths[1]; ++j) {

```
167 (*this)(i, j) = other(i, j);
168 }
169 }
```

References gko::accessor::row\_major< ValueType, Dimensionality >::lengths.

## 26.84.2.2 length()

Returns the length in dimension  ${\tt dimension}.$ 

#### **Parameters**

dimension a dimension index
-----------------------------

#### Returns

length in dimension dimension

References gko::accessor::row\_major< ValueType, Dimensionality >::lengths.

#### 26.84.2.3 operator()() [1/2]

Returns the sub-range spanning the range (rows, cols)

# **Parameters**

rows	row span
cols	column span

### Returns

sub-range spanning the range (rows, cols)

References gko::span::begin, gko::accessor::row\_major< ValueType, Dimensionality >::data, gko::span::end, gko::span::is\_valid(), gko::accessor::row\_major< ValueType, Dimensionality >::lengths, and gko::accessor::row—major< ValueType, Dimensionality >::stride.

#### 26.84.2.4 operator()() [2/2]

Returns the data element at position (row, col)

#### **Parameters**

row	row index
col	column index

#### Returns

data element at (row, col)

References gko::accessor::row\_major< ValueType, Dimensionality >::data, gko::accessor::row\_major< Value ← Type, Dimensionality >::lengths, and gko::accessor::row\_major< ValueType, Dimensionality >::stride.

The documentation for this class was generated from the following file:

ginkgo/core/base/range\_accessors.hpp (f1a4eb68b)

# 26.85 gko::matrix::Sellp< ValueType, IndexType > Class Template Reference

SELL-P is a matrix format similar to ELL format.

#include <ginkgo/core/matrix/sellp.hpp>

## **Public Member Functions**

• void read (const mat\_data &data) override

Reads a matrix from a matrix\_data structure.

• void write (mat\_data &data) const override

Writes a matrix to a matrix\_data structure.

value\_type \* get\_values () noexcept

Returns the values of the matrix.

const value\_type \* get\_const\_values () const noexcept

Returns the values of the matrix.

• index type \* get col idxs () noexcept

Returns the column indexes of the matrix.

const index\_type \* get\_const\_col\_idxs () const noexcept

Returns the column indexes of the matrix.

• size\_type \* get\_slice\_lengths () noexcept

Returns the lengths(columns) of slices.

Returns the offsets of slices.

const size\_type \* get\_const\_slice\_sets () const noexcept

Returns the offsets of slices.

• size\_type get\_slice\_size () const noexcept

Returns the size of a slice.

size\_type get\_stride\_factor () const noexcept

Returns the stride factor(t) of SELL-P.

size\_type get\_total\_cols () const noexcept

Returns the total column number.

• size\_type get\_num\_stored\_elements () const noexcept

Returns the number of elements explicitly stored in the matrix.

• value\_type & val\_at (size\_type row, size\_type slice\_set, size\_type idx) noexcept

Returns the idx-th non-zero element of the row-th row with slice\_set slice set.

value\_type val\_at (size\_type row, size\_type slice\_set, size\_type idx) const noexcept

Returns the idx-th non-zero element of the row-th row with slice\_set slice set.

• index\_type & col\_at (size\_type row, size\_type slice\_set, size\_type idx) noexcept

Returns the idx-th column index of the row-th row with slice\_set slice set.

• index\_type col\_at (size\_type row, size\_type slice\_set, size\_type idx) const noexcept

Returns the idx-th column index of the row-th row with slice\_set slice set.

# 26.85.1 Detailed Description

```
\label{template} $$ $$ template < typename \ ValueType = default\_precision, typename \ IndexType = int32 > class \ gko::matrix::Sellp < ValueType, \ IndexType > $$
```

SELL-P is a matrix format similar to ELL format.

The difference is that SELL-P format divides rows into smaller slices and store each slice with ELL format.

#### **Template Parameters**

ValueType	precision of matrix elements
IndexType	precision of matrix indexes

#### 26.85.2 Member Function Documentation

#### 26.85.2.1 col\_at() [1/2]

Returns the  ${\tt idx}$ -th column index of the  ${\tt row}$ -th row with  ${\tt slice}\_{\tt set}$  slice set.

#### **Parameters**

row	the row of the requested element in the slice
slice_set	the slice set of the slice
idx	the idx-th stored element of the row in the slice

#### Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the CPU results in a runtime error)

```
260 {
261     return this
262     ->get_const_col_idxs()[this->linearize_index(row, slice_set, idx)];
263 }
```

#### 26.85.2.2 col\_at() [2/2]

Returns the idx-th column index of the row-th row with slice\_set slice set.

#### **Parameters**

row	the row of the requested element in the slice
slice_set	the slice set of the slice
idx	the idx-th stored element of the row in the slice

### Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the CPU results in a runtime error)

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::Sellp< ValueType, IndexType >::get_num_stored_elements ( ) const [inline],
[noexcept]
```

Returns the number of elements explicitly stored in the matrix.

#### Returns

the number of elements explicitly stored in the matrix

References gko::Array< ValueType >::get\_num\_elems().

## 26.85.2.9 get\_slice\_lengths()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type* gko::matrix::Sellp< ValueType, IndexType >::get_slice_lengths () [inline], [noexcept]
```

Returns the lengths(columns) of slices.

#### Returns

the lengths(columns) of slices.

References gko::Array< ValueType >::get\_data().

## 26.85.2.10 get\_slice\_sets()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type* gko::matrix::Sellp< ValueType, IndexType >::get_slice_sets () [inline], [noexcept]
```

Returns the offsets of slices.

Returns

the offsets of slices.

References gko::Array< ValueType >::get data().

#### 26.85.2.11 get\_slice\_size()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::Sellp< ValueType, IndexType >::get_slice_size ( ) const [inline],
[noexcept]
```

Returns the size of a slice.

Returns

the size of a slice.

#### 26.85.2.12 get\_stride\_factor()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::Sellp< ValueType, IndexType >::get_stride_factor ( ) const [inline],
[noexcept]
```

Returns the stride factor(t) of SELL-P.

Returns

the stride factor(t) of SELL-P.

## 26.85.2.13 get\_total\_cols()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::Sellp< ValueType, IndexType >::get_total_cols ( ) const [inline],
[noexcept]
```

Returns the total column number.

Returns

the total column number.

## 26.85.2.14 get\_values()

```
template<typename ValueType = default_precision, typename IndexType = int32>
value_type* gko::matrix::Sellp< ValueType, IndexType >::get_values ( ) [inline], [noexcept]
```

Returns the values of the matrix.

## Returns

the values of the matrix.

References gko::Array< ValueType >::get\_data().

#### 26.85.2.15 read()

Reads a matrix from a matrix\_data structure.

#### **Parameters**

```
data the matrix_data structure
```

 $Implements\ gko:: Readable From Matrix Data < Value Type,\ Index Type >.$ 

# 26.85.2.16 val\_at() [1/2]

Returns the idx-th non-zero element of the row-th row with slice\_set slice set.

## **Parameters**

row	the row of the requested element in the slice
slice_set	the slice set of the slice
idx	the idx-th stored element of the row in the slice

#### Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the CPU results in a runtime error)

References gko::Array< ValueType >::get const data().

# 26.85.2.17 val\_at() [2/2]

Returns the idx-th non-zero element of the row-th row with slice\_set slice set.

#### **Parameters**

row	the row of the requested element in the slice
slice_set the slice set of the slice	
idx	the idx-th stored element of the row in the slice

#### Note

the method has to be called on the same Executor the matrix is stored at (e.g. trying to call this method on a GPU matrix from the CPU results in a runtime error)

References gko::Array< ValueType >::get\_data().

#### 26.85.2.18 write()

Writes a matrix to a matrix\_data structure.

#### **Parameters**

```
data the matrix_data structure
```

Implements gko::WritableToMatrixData< ValueType, IndexType >.

The documentation for this class was generated from the following files:

# 26.86 gko::span Struct Reference

A span is a lightweight structure used to create sub-ranges from other ranges.

```
#include <ginkgo/core/base/range.hpp>
```

## **Public Member Functions**

• constexpr span (size\_type point) noexcept

Creates a span representing a point point.

• constexpr span (size\_type begin, size\_type end) noexcept

Creates a span.

· constexpr bool is\_valid () const

Checks if a span is valid.

# **Public Attributes**

· const size\_type begin

Beginning of the span.

· const size\_type end

End of the span.

# 26.86.1 Detailed Description

A span is a lightweight structure used to create sub-ranges from other ranges.

A span s represents a contiguous set of indexes in one dimension of the range, starting on index s.begin (inclusive) and ending at index s.end (exclusive). A span is only valid if its starting index is smaller than its ending index.

Spans can be compared using the == and != operators. Two spans are identical if both their begin and end values are identical.

Spans also have two distinct partial orders defined on them:

```
1. x < y (y > x) if and only if x.end < y.begin
```

```
2. x \ll y (y \gg x) if and only if x.end \ll y.begin
```

Note that the orders are in fact partial - there are spans x and y for which none of the following inequalities holds: x < y, x > y, x == y, x <= y, x >= y. An example are spans  $span\{0, 2\}$  and  $span\{1, 3\}$ .

In addition, <= is a distinct order from <, and not just an extension of the strict order to its weak equivalent. Thus, x <= y is not equivalent to  $x < y \mid \mid x == y$ .

## 26.86.2 Constructor & Destructor Documentation

# 26.86.2.1 span() [1/2]

Creates a span representing a point point.

The begin of this span is set to point, and the end to point + 1.

#### **Parameters**

## 26.86.2.2 span() [2/2]

Creates a span.

#### **Parameters**

begin	the beginning of the span
end	the end of the span

References begin.

# 26.86.3 Member Function Documentation

# 26.86.3.1 is\_valid()

# 26.87 gko::matrix::SparsityCsr< ValueType, IndexType > Class Template Reference

SparsityCsr is a matrix format which stores only the sparsity pattern of a sparse matrix by compressing each row of the matrix (compressed sparse row format).

```
#include <ginkgo/core/matrix/sparsity_csr.hpp>
```

#### **Public Member Functions**

· void read (const mat data &data) override

Reads a matrix from a matrix\_data structure.

· void write (mat data &data) const override

Writes a matrix to a matrix\_data structure.

std::unique\_ptr< LinOp > transpose () const override

Returns a LinOp representing the transpose of the Transposable object.

std::unique\_ptr< LinOp > conj\_transpose () const override

Returns a LinOp representing the conjugate transpose of the Transposable object.

• std::unique\_ptr< SparsityCsr > to\_adjacency\_matrix () const

Transforms the sparsity matrix to an adjacency matrix.

void sort\_by\_column\_index ()

Sorts each row by column index.

index type \* get col idxs () noexcept

Returns the column indices of the matrix.

const index\_type \* get\_const\_col\_idxs () const noexcept

Returns the column indices of the matrix.

index\_type \* get\_row\_ptrs () noexcept

Returns the row pointers of the matrix.

const index\_type \* get\_const\_row\_ptrs () const noexcept

Returns the row pointers of the matrix.

value type \* get value () noexcept

Returns the value stored in the matrix.

const value\_type \* get\_const\_value () const noexcept

Returns the value stored in the matrix.

• size\_type get\_num\_nonzeros () const noexcept

Returns the number of elements explicitly stored in the matrix.

# 26.87.1 Detailed Description

template<typename ValueType = default\_precision, typename IndexType = int32> class gko::matrix::SparsityCsr< ValueType, IndexType >

SparsityCsr is a matrix format which stores only the sparsity pattern of a sparse matrix by compressing each row of the matrix (compressed sparse row format).

The values of the nonzero elements are stored as a value array of length 1. All the values in the matrix are equal to this value. By default, this value is set to 1.0. A row pointer array also stores the linearized starting index of each row. An additional column index array is used to identify the column where a nonzero is present.

# **Template Parameters**

ValueType	precision of vectors in apply
IndexType	precision of matrix indexes

# 26.87.2 Member Function Documentation

# 26.87.2.1 conj\_transpose()

```
template<typename ValueType = default_precision, typename IndexType = int32>
std::unique_ptr<LinOp> gko::matrix::SparsityCsr< ValueType, IndexType >::conj_transpose ( )
const [override], [virtual]
```

Returns a LinOp representing the conjugate transpose of the Transposable object.

## Returns

a pointer to the new conjugate transposed object

Implements gko::Transposable.

# 26.87.2.2 get\_col\_idxs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
index_type* gko::matrix::SparsityCsr< ValueType, IndexType >::get_col_idxs ( ) [inline],
[noexcept]
```

Returns the column indices of the matrix.

#### Returns

the column indices of the matrix.

```
126 { return col_idxs_.get_data(); }
```

References gko::Array< ValueType >::get\_data().

# 26.87.2.3 get\_const\_col\_idxs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const index_type* gko::matrix::SparsityCsr< ValueType, IndexType >::get_const_col_idxs ( )
const [inline], [noexcept]
```

Returns the column indices of the matrix.

# Returns

the column indices of the matrix.

# Note

This is the constant version of the function, which can be significantly more memory efficient than the non-constant version, so always prefer this version.

References gko::Array< ValueType >::get\_const\_data().

## 26.87.2.4 get\_const\_row\_ptrs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const index_type* gko::matrix::SparsityCsr< ValueType, IndexType >::get_const_row_ptrs ( )
const [inline], [noexcept]
```

Returns the row pointers of the matrix.

#### Returns

the row pointers of the matrix.

#### Note

This is the constant version of the function, which can be significantly more memory efficient than the non-constant version, so always prefer this version.

References gko::Array< ValueType >::get\_const\_data().

## 26.87.2.5 get\_const\_value()

```
template<typename ValueType = default_precision, typename IndexType = int32>
const value_type* gko::matrix::SparsityCsr< ValueType, IndexType >::get_const_value ( ) const
[inline], [noexcept]
```

Returns the value stored in the matrix.

#### Returns

the value of the matrix.

#### Note

This is the constant version of the function, which can be significantly more memory efficient than the non-constant version, so always prefer this version.

References gko::Array< ValueType >::get\_const\_data().

# 26.87.2.6 get\_num\_nonzeros()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::SparsityCsr< ValueType, IndexType >::get_num_nonzeros ( ) const [inline],
[noexcept]
```

Returns the number of elements explicitly stored in the matrix.

#### Returns

the number of elements explicitly stored in the matrix

References gko::Array< ValueType >::get\_num\_elems().

# 26.87.2.7 get\_row\_ptrs()

```
template<typename ValueType = default_precision, typename IndexType = int32>
index_type* gko::matrix::SparsityCsr< ValueType, IndexType >::get_row_ptrs ( ) [inline],
[noexcept]
```

Returns the row pointers of the matrix.

#### Returns

the row pointers of the matrix.

References gko::Array< ValueType >::get\_data().

# 26.87.2.8 get\_value()

```
template<typename ValueType = default_precision, typename IndexType = int32>
value_type* gko::matrix::SparsityCsr< ValueType, IndexType >::get_value ( ) [inline], [noexcept]
```

Returns the value stored in the matrix.

#### Returns

the value of the matrix.

References gko::Array< ValueType >::get\_data().

# 26.87.2.9 read()

Reads a matrix from a matrix\_data structure.

# **Parameters**

```
data the matrix_data structure
```

 $Implements\ gko:: Readable From Matrix Data < Value Type,\ Index Type >.$ 

# 26.87.2.10 to\_adjacency\_matrix()

```
template<typename ValueType = default_precision, typename IndexType = int32>
```

```
std::unique\_ptr < SparsityCsr > gko::matrix::SparsityCsr < ValueType, IndexType >::to\_adjacency \leftarrow \_matrix ( ) const
```

Transforms the sparsity matrix to an adjacency matrix.

As the adjacency matrix has to be square, the input SparsityCsr matrix for this function to work has to be square.

Note

The adjacency matrix in this case is the sparsity pattern but with the diagonal ones removed. This is mainly used for the reordering/partitioning as taken in by graph libraries such as METIS.

## 26.87.2.11 transpose()

```
template<typename ValueType = default_precision, typename IndexType = int32>
std::unique_ptr<LinOp> gko::matrix::SparsityCsr< ValueType, IndexType >::transpose ( ) const
[override], [virtual]
```

Returns a LinOp representing the transpose of the Transposable object.

## Returns

a pointer to the new transposed object

Implements gko::Transposable.

## 26.87.2.12 write()

Writes a matrix to a matrix\_data structure.

#### **Parameters**

```
data the matrix_data structure
```

Implements gko::WritableToMatrixData< ValueType, IndexType >.

The documentation for this class was generated from the following files:

# 26.88 gko::stopping\_status Class Reference

This class is used to keep track of the stopping status of one vector.

#include <ginkgo/core/stop/stopping\_status.hpp>

## **Public Member Functions**

· bool has stopped () const noexcept

Check if any stopping criteria was fulfilled.

bool has\_converged () const noexcept

Check if convergence was reached.

bool is\_finalized () const noexcept

Check if the corresponding vector stores the finalized result.

• uint8 get\_id () const noexcept

Get the id of the stopping criterion which caused the stop.

• void reset () noexcept

Clear all flags.

void stop (uint8 id, bool set\_finalized=true) noexcept

Call if a stop occured due to a hard limit (and convergence was not reached).

void converge (uint8 id, bool set\_finalized=true) noexcept

Call if convergence occured.

• void finalize () noexcept

Set the result to be finalized (it needs to be stopped or converged first).

# **Friends**

- bool operator== (const stopping\_status &x, const stopping\_status &y) noexcept Checks if two stopping statuses are equivalent.
- bool operator!= (const stopping\_status &x, const stopping\_status &y) noexcept Checks if two stopping statuses are different.

# 26.88.1 Detailed Description

This class is used to keep track of the stopping status of one vector.

## 26.88.2 Member Function Documentation

# 26.88.2.1 converge()

Call if convergence occured.

#### **Parameters**

id	id of the stopping criteria.	
set_finalized	Controls if the current version should count as finalized (set to true) or not (set to false).	1

References has\_stopped().

# 26.88.2.2 get\_id()

```
uint8 gko::stopping_status::get_id ( ) const [inline], [noexcept]
```

Get the id of the stopping criterion which caused the stop.

## Returns

Returns the id of the stopping criterion which caused the stop.

Referenced by has\_stopped().

# 26.88.2.3 has\_converged()

```
bool gko::stopping_status::has_converged ( ) const [inline], [noexcept]
```

Check if convergence was reached.

## Returns

Returns true if convergence was reached.

# 26.88.2.4 has\_stopped()

```
bool gko::stopping_status::has_stopped ( ) const [inline], [noexcept]
```

Check if any stopping criteria was fulfilled.

# Returns

Returns true if any stopping criteria was fulfilled.

References get\_id().

Referenced by converge(), finalize(), and stop().

# 26.88.2.5 is\_finalized()

```
bool gko::stopping_status::is_finalized ( ) const [inline], [noexcept]
```

Check if the corresponding vector stores the finalized result.

#### Returns

Returns true if the corresponding vector stores the finalized result.

## 26.88.2.6 stop()

Call if a stop occured due to a hard limit (and convergence was not reached).

#### **Parameters**

id	id of the stopping criteria.
set_finalized	Controls if the current version should count as finalized (set to true) or not (set to false).

References has\_stopped().

# 26.88.3 Friends And Related Function Documentation

# 26.88.3.1 operator"!=

Checks if two stopping statuses are different.

#### **Parameters**

X	a stopping status
У	a stopping status

# Returns

```
true if and only if ! (x == y)
```

# 26.88.3.2 operator==

Checks if two stopping statuses are equivalent.

#### **Parameters**

Х	a stopping status
у	a stopping status

#### Returns

true if and only if both x and y have the same mask and converged and finalized state

The documentation for this class was generated from the following file:

ginkgo/core/stop/stopping\_status.hpp (f1a4eb68b)

# 26.89 gko::matrix::Hybrid< ValueType, IndexType >::strategy\_type Class Reference

strategy\_type is to decide how to set the hybrid config.

```
#include <ginkgo/core/matrix/hybrid.hpp>
```

## **Public Member Functions**

• strategy\_type ()

Creates a strategy\_type.

Computes the config of the Hybrid matrix (ell\_num\_stored\_elements\_per\_row and coo\_nnz).

size\_type get\_ell\_num\_stored\_elements\_per\_row () const noexcept

Returns the number of stored elements per row of the ell part.

size\_type get\_coo\_nnz () const noexcept

Returns the number of nonzeros of the coo part.

virtual size\_type compute\_ell\_num\_stored\_elements\_per\_row (Array< size\_type > \*row\_nnz) const =0
 Computes the number of stored elements per row of the ell part.

# 26.89.1 Detailed Description

template<typename ValueType = default\_precision, typename IndexType = int32> class gko::matrix::Hybrid< ValueType, IndexType >::strategy\_type

strategy\_type is to decide how to set the hybrid config.

It computes the number of stored elements per row of the ell part and then set the number of residual nonzeros as the number of nonzeros of the coo part.

The practical strategy method should inherit strategy\_type and implement its compute\_ell\_num\_stored\_← elements\_per\_row function.

#### 26.89.2 Member Function Documentation

# 26.89.2.1 compute\_ell\_num\_stored\_elements\_per\_row()

```
template<typename ValueType = default_precision, typename IndexType = int32> virtual size_type gko::matrix::Hybrid< ValueType, IndexType >::strategy_type::compute_ell_← num_stored_elements_per_row (

Array< size_type > * row_nnz ) const [pure virtual]
```

Computes the number of stored elements per row of the ell part.

# Parameters

v_nnz the number of nonz	eros of each row
--------------------------	------------------

## Returns

the number of stored elements per row of the ell part

Implemented in gko::matrix::Hybrid< ValueType, IndexType >::automatic, gko::matrix::Hybrid< ValueType, IndexType >::minimal\_stegko::matrix::Hybrid< ValueType, IndexType >::imbalance\_bounded\_limit, gko::matrix::Hybrid< ValueType, IndexType >::imbalance\_and gko::matrix::Hybrid< ValueType, IndexType >::column limit.

Referenced by gko::matrix::Hybrid< ValueType, IndexType >::strategy\_type::compute\_hybrid\_config().

#### 26.89.2.2 compute\_hybrid\_config()

Computes the config of the Hybrid matrix (ell\_num\_stored\_elements\_per\_row and coo\_nnz).

For now, it copies row\_nnz to the reference executor and performs all operations on the reference executor.

#### **Parameters**

row_nnz	the number of nonzeros of each row	
ell_num_stored_elements_per_row	the output number of stored elements per row of the ell part	
coo_nnz	the output number of nonzeros of the coo part	

References gko::matrix::Hybrid< ValueType, IndexType >::strategy\_type::compute\_ell\_num\_stored\_elements\_ per\_row(), gko::Array< ValueType >::get\_executor(), and gko::Array< ValueType >::get\_num\_elems().

## 26.89.2.3 get\_coo\_nnz()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::Hybrid< ValueType, IndexType >::strategy_type::get_coo_nnz ( ) const
[inline], [noexcept]
```

Returns the number of nonzeros of the coo part.

#### Returns

the number of nonzeros of the coo part

## 26.89.2.4 get ell num stored elements per row()

```
template<typename ValueType = default_precision, typename IndexType = int32>
size_type gko::matrix::Hybrid< ValueType, IndexType >::strategy_type::get_ell_num_stored_
elements_per_row ( ) const [inline], [noexcept]
```

Returns the number of stored elements per row of the ell part.

# Returns

the number of stored elements per row of the ell part

The documentation for this class was generated from the following file:

• ginkgo/core/matrix/hybrid.hpp (4b82e692f)

# 26.90 gko::log::Stream < ValueType > Class Template Reference

Stream is a Logger which logs every event to a stream.

#include <ginkgo/core/log/stream.hpp>

## **Static Public Member Functions**

Creates a Stream logger.

# 26.90.1 Detailed Description

```
template<typename ValueType = default_precision> class gko::log::Stream< ValueType >
```

Stream is a Logger which logs every event to a stream.

This can typically be used to log to a file or to the console.

## **Template Parameters**

ValueType	the type of values stored in the class (i.e. ValueType template parameter of the concrete Loggable	1
	this class will log)	

# 26.90.2 Member Function Documentation

#### 26.90.2.1 create()

Creates a Stream logger.

This dynamically allocates the memory, constructs the object and returns an std::unique\_ptr to this object.

## **Parameters**

exec	the executor	
enabled_events	the events enabled for this logger. By default all events.	
os	the stream used for this logger	
verbose	whether we want detailed information or not. This includes always printing residuals and other information which can give a large output.	

#### Returns

an std::unique\_ptr to the the constructed object

The documentation for this class was generated from the following file:

• ginkgo/core/log/stream.hpp (f1a4eb68b)

# 26.91 gko::StreamError Class Reference

StreamError is thrown if accessing a stream failed.

```
#include <ginkgo/core/base/exception.hpp>
```

## **Public Member Functions**

• StreamError (const std::string &file, int line, const std::string &func, const std::string &message)

Initializes a file access error.

# 26.91.1 Detailed Description

StreamError is thrown if accessing a stream failed.

## 26.91.2 Constructor & Destructor Documentation

## 26.91.2.1 StreamError()

Initializes a file access error.

#### **Parameters**

file	The name of the offending source file
line	The source code line number where the error occurred
func	The name of the function that tried to access the file
message	The error message

The documentation for this class was generated from the following file:

• ginkgo/core/base/exception.hpp (6e8865457)

# 26.92 gko::temporary\_clone < T > Class Template Reference

A temporary\_clone is a special smart pointer-like object that is designed to hold an object temporarily copied to another executor.

```
#include <ginkgo/core/base/utils.hpp>
```

# **Public Member Functions**

temporary\_clone (std::shared\_ptr< const Executor > exec, pointer ptr)

Creates a temporary\_clone.

• T \* get () const

Returns the object held by temporary\_clone.

• T \* operator-> () const

Calls a method on the underlying object.

# 26.92.1 Detailed Description

```
\label{template} \begin{split} \text{template} &< \text{typename T}> \\ \text{class gko::temporary\_clone} &< \text{T}> \end{split}
```

A temporary\_clone is a special smart pointer-like object that is designed to hold an object temporarily copied to another executor.

After the temporary\_clone goes out of scope, the stored object will be copied back to its original location. This class is optimized to avoid copies if the object is already on the correct executor, in which case it will just hold a reference to that object, without performing the copy.

**Template Parameters** 

```
T the type of object held in the temporary_clone
```

## 26.92.2 Constructor & Destructor Documentation

#### 26.92.2.1 temporary\_clone()

Creates a temporary\_clone.

#### **Parameters**

exec	the executor where the clone will be created
ptr	a pointer to the object of which the clone will be created

References gko::clone().

# 26.92.3 Member Function Documentation

## 26.92.3.1 get()

```
template<typename T >
T* gko::temporary_clone< T >::get ( ) const [inline]
```

Returns the object held by temporary\_clone.

## Returns

the object held by temporary\_clone

# 26.92.3.2 operator->()

```
template<typename T >
T* gko::temporary_clone< T >::operator-> ( ) const [inline]
```

Calls a method on the underlying object.

# Returns

the underlying object

The documentation for this class was generated from the following file:

• ginkgo/core/base/utils.hpp (ffa4bb4e4)

# 26.93 gko::stop::Time Class Reference

The Time class is a stopping criterion which stops the iteration process after a certain amout of time has passed.

```
#include <ginkgo/core/stop/time.hpp>
```

# 26.93.1 Detailed Description

The Time class is a stopping criterion which stops the iteration process after a certain amout of time has passed.

The documentation for this class was generated from the following file:

• ginkgo/core/stop/time.hpp (2e1635cba)

# 26.94 gko::Transposable Class Reference

Linear operators which support transposition should implement the Transposable interface.

```
#include <ginkgo/core/base/lin_op.hpp>
```

## **Public Member Functions**

- virtual std::unique\_ptr< LinOp > transpose () const =0
   Returns a LinOp representing the transpose of the Transposable object.
- virtual std::unique\_ptr< LinOp > conj\_transpose () const =0
   Returns a LinOp representing the conjugate transpose of the Transposable object.

# 26.94.1 Detailed Description

Linear operators which support transposition should implement the Transposable interface.

It provides two functionalities, the normal transpose and the conjugate transpose.

The normal transpose returns the transpose of the linear operator without changing any of its elements representing the operation,  $B = A^T$ .

The conjugate transpose returns the conjugate of each of the elements and additionally transposes the linear operator representing the operation,  $B=A^H$ .

# 26.94.1.1 Example: Transposing a Csr matrix:

```
{c++}
//Transposing an object of LinOp type.
//The object you want to transpose.
auto op = matrix::Csr::create(exec);
//Transpose the object by first converting it to a transposable type.
auto trans = op->transpose();
```

# 26.94.2 Member Function Documentation

# 26.94.2.1 conj\_transpose()

```
virtual std::unique_ptr<LinOp> gko::Transposable::conj_transpose ( ) const [pure virtual]
```

Returns a LinOp representing the conjugate transpose of the Transposable object.

Returns

a pointer to the new conjugate transposed object

Implemented in gko::matrix::Csr< ValueType, IndexType >, gko::matrix::Dense< ValueType >, and gko::matrix::SparsityCsr< ValueType

## 26.94.2.2 transpose()

```
virtual std::unique_ptr<LinOp> gko::Transposable::transpose ( ) const [pure virtual]
```

Returns a LinOp representing the transpose of the Transposable object.

Returns

a pointer to the new transposed object

 $Implemented \ in \ gko::matrix::Csr<\ Value\ Type,\ Index\ Type>,\ gko::matrix::Dense<\ Value\ Type>,\ and\ gko::matrix::Sparsity\ Csr<\ Value\ Type>,\ and\ gko::matrix::gko::matrix::gko::matrix::gko::matrix::gko::matrix::gko::matrix::gko::matrix::gko::matrix::gko::matrix::gko::m$

# 26.95 gko::stop::Criterion::Updater Class Reference

The Updater class serves for convenient argument passing to the Criterion's check function.

```
#include <ginkgo/core/stop/criterion.hpp>
```

# **Public Member Functions**

- Updater (const Updater &)=delete
  - Prevent copying and moving the object This is to enforce the use of argument passing and calling check at the same time.
- bool check (uint8 stoppingId, bool setFinalized, Array < stopping\_status > \*stop\_status, bool \*one\_changed)
   const

Calls the parent Criterion object's check method.

# 26.95.1 Detailed Description

The Updater class serves for convenient argument passing to the Criterion's check function.

The pattern used is a Builder, except Updater builds a function's arguments before calling the function itself, and does not build an object. This allows calling a Criterion's check in the form of: stop\_criterion->update() .num\_\circ} iterations(num\_iterations) .residual\_norm(residual\_norm) .residual(residual) .solution(solution) .check(converged);

If there is a need for a new form of data to pass to the Criterion, it should be added here.

## 26.95.2 Member Function Documentation

## 26.95.2.1 check()

Calls the parent Criterion object's check method.

References gko::stop::Criterion::check().

The documentation for this class was generated from the following file:

• ginkgo/core/stop/criterion.hpp (da7880906)

# 26.96 gko::solver::UpperTrs< ValueType, IndexType > Class Template Reference

UpperTrs is the triangular solver which solves the system U x = b, when U is an upper triangular matrix.

```
#include <ginkgo/core/solver/upper_trs.hpp>
```

# **Public Member Functions**

• std::shared\_ptr< const matrix::Csr< ValueType, IndexType > > get\_system\_matrix () const Gets the system operator (CSR matrix) of the linear system.

# 26.96.1 Detailed Description

```
\label{template} $$ $$ template < typename \ ValueType = default\_precision, typename \ IndexType = int32 > class \ gko::solver::UpperTrs < ValueType, \ IndexType > $$
```

UpperTrs is the triangular solver which solves the system U x = b, when U is an upper triangular matrix.

It works best when passing in a matrix in CSR format. If the matrix is not in CSR, then the generate step converts it into a CSR matrix. The generation fails if the matrix is not convertible to CSR.

Note

As the constructor uses the copy and convert functionality, it is not possible to create a empty solver or a solver with a matrix in any other format other than CSR, if none of the executor modules are being compiled with.

## **Template Parameters**

ValueType	precision of matrix elements
IndexType	precision of matrix indices

# 26.96.2 Member Function Documentation

## 26.96.2.1 get\_system\_matrix()

```
template<typename ValueType = default_precision, typename IndexType = int32>
std::shared_ptr<const matrix::Csr<ValueType, IndexType> > gko::solver::UpperTrs< ValueType,
IndexType>::get_system_matrix ( ) const [inline]
```

Gets the system operator (CSR matrix) of the linear system.

#### Returns

the system operator (CSR matrix)

# 26.97 gko::ValueMismatch Class Reference

ValueMismatch is thrown if two values are not equal.

```
#include <ginkgo/core/base/exception.hpp>
```

# **Public Member Functions**

• ValueMismatch (const std::string &file, int line, const std::string &func, size\_type val1, size\_type val2, const std::string &clarification)

Initializes a value mismatch error.

# 26.97.1 Detailed Description

ValueMismatch is thrown if two values are not equal.

## 26.97.2 Constructor & Destructor Documentation

## 26.97.2.1 ValueMismatch()

Initializes a value mismatch error.

#### **Parameters**

file	The name of the offending source file
line	The source code line number where the error occurred
func	The function name where the error occurred
val1	The first value to be compared.
val2	The second value to be compared.
clarification	An additional message further describing the error

# 26.98 gko::version Struct Reference

This structure is used to represent versions of various Ginkgo modules.

```
#include <ginkgo/core/base/version.hpp>
```

# **Public Attributes**

· const uint64 major

The major version number.

· const uint64 minor

The minor version number.

· const uint64 patch

The patch version number.

· const char \*const tag

Addition tag string that describes the version in more detail.

# 26.98.1 Detailed Description

This structure is used to represent versions of various Ginkgo modules.

Version structures can be compared using the usual relational operators.

## 26.98.2 Member Data Documentation

## 26.98.2.1 tag

```
const char* const gko::version::tag
```

Addition tag string that describes the version in more detail.

It does not participate in comparisons.

Referenced by gko::operator<<().

The documentation for this struct was generated from the following file:

ginkgo/core/base/version.hpp (42eeea818)

# 26.99 gko::version\_info Class Reference

Ginkgo uses version numbers to label new features and to communicate backward compatibility guarantees:

```
#include <ginkgo/core/base/version.hpp>
```

## **Static Public Member Functions**

static const version\_info & get ()
 Returns an instance of version\_info.

## **Public Attributes**

· version header\_version

Contains version information of the header files.

version core\_version

Contains version information of the core library.

• version reference\_version

Contains version information of the reference module.

version omp\_version

Contains version information of the OMP module.

version cuda\_version

Contains version information of the CUDA module.

# 26.99.1 Detailed Description

Ginkgo uses version numbers to label new features and to communicate backward compatibility guarantees:

- 1. Versions with different major version number have incompatible interfaces (parts of the earlier interface may not be present anymore, and new interfaces can appear).
- 2. Versions with the same major number X, but different minor numbers Y1 and Y2 numbers keep the same interface as version X.0.0, but additions to the interface in X.0.0 present in X.Y1.0 may not be present in X.Y2.0 and vice versa.
- 3. Versions with the same major an minor version numbers, but different patch numbers have exactly the same interface, but the functionality may be different (something that is not implemented or has a bug in an earlier version may have this implemented or fixed in a later version).

This structure provides versions of different parts of Ginkgo: the headers, the core and the kernel modules (reference, OpenMP, CUDA). To obtain an instance of version\_info filled with information about the current version of Ginkgo, call the version info::get() static method.

## 26.99.2 Member Function Documentation

# 26.99.2.1 get()

```
static const version_info& gko::version_info::get ( ) [inline], [static]
```

Returns an instance of version\_info.

## Returns

an instance of version info

#### 26.99.3 Member Data Documentation

# 26.99.3.1 core\_version

```
version gko::version_info::core_version
```

Contains version information of the core library.

This is the version of the static/shared library called "ginkgo".

# 26.99.3.2 cuda\_version

```
version gko::version_info::cuda_version
```

Contains version information of the CUDA module.

This is the version of the static/shared library called "ginkgo\_cuda".

#### 26.99.3.3 omp\_version

```
version gko::version_info::omp_version
```

Contains version information of the OMP module.

This is the version of the static/shared library called "ginkgo\_omp".

## 26.99.3.4 reference\_version

```
version gko::version_info::reference_version
```

Contains version information of the reference module.

This is the version of the static/shared library called "ginkgo\_reference".
